Introduction

Warnings

Throughout this manual, icons will be used to call attention to certain areas of text. These icons represent safety warnings, cautions, and notes.

⚠️ WARNING: Denotes operating procedures and practices that may result in personal injury and/or equipment damage if not correctly followed.

⚠️ CAUTION: Denotes operating procedures and practices that may result in equipment damage if not correctly followed.

آخر نوتي: Denotes useful information or procedures.

Throughout this manual it is assumed that field personnel are well qualified in the installation of elevator equipment. No attempt has been made to define terms or procedures that should be familiar to a qualified elevator mechanic.

آخر نوتي: It is assumed that all switches for slowdown, stop, and over travel limits at both terminal landings have been checked for proper type, placement, and operation.

⚠️ CAUTION: Equipment installation must be in compliance with all Local and applicable Elevator and Electrical Codes and regulations

This manual is intended only to acquaint the service technician with the information required to successfully install the microprocessor-based elevator controller. Field personnel must be familiar with all codes and regulations pertaining to the safe installation and operation of the elevator system.

آخر نوتي: Installation and wiring must be in accordance with the National Electrical Code and consistent with all local codes, and National elevator codes and regulations. The AC power supply to this equipment must be provided through a proper fused disconnect or circuit breaker. Improper protection may create a hazardous condition.

آخر نوتي: Wiring to controller terminals must be done in a neat and careful manner. Stranded wire conductors must be twisted together to avoid strands that would create potential shorts if left out of terminals. All controller and field terminals and cable connectors must be checked for proper seating and tightness. When connecting flat cable connectors, be certain to match pin #1 marks (arrow symbol on connectors, red stripe on cable) to prevent damage.

⚠️ CAUTION: Restrict access to elevator control equipment and apparatus to qualified personnel only.
Section 1 – Overview

1.1 Product Description

ELEVATOR CONTROLS CORPORATION model V900-PVF microcomputer based traction Controller utilizes state-of-the-art large scale integrated circuits built into a high performance modular circuit board design, in such a way as to optimize reliability and minimize installation and maintenance costs.

The Basic Simplex System contains a Computer Microprocessor Board, P8 for standard controller or PIO9 for Prodigy Controllers, I/O Boards, a Relay Interface Board, and a Position Velocity Feedback computer in addition to the Microprocessor Power Supply, Control Transformer, and Starter. The motor control is a DC SCR elevator drive or an AC Variable Voltage Variable Frequency elevator drive unit.

The Position Velocity Feedback computer, Smart Drive Interface (SDI), is included to provide shaft position feedback and optimized velocity speed profile pattern generation for each elevator run.

Group Controller G900-XL is available for the control of up to 16 cars.

A simple to use, powerful diagnostic station is built into the Computer Microprocessor Board which includes capabilities for complete on-site re-programming of the elevator “Personality” parameters via the LCD display.

Video Display, Modem Remote Communications, and Hardcopy Elevator performance printing are all available by means of an output connector capable of driving a standard PC and, including notebook and palm top computers.

Figure 1.2 - Typical V900-PVF Prodigy Controller Layout
1.3 Components General Function and Description

1.3.1.1 P8 (V900/ H900 Standard Controller Only)
The P8 board is universal to all V900/ H900 standard series of control systems, and is used in all types of elevators from hydraulic to traction, and as a main Group dispatcher microprocessor. The P8 board utilizes high speed, microprocessor technology with a high level of system integration.

NOTE: P8 microprocessor board may also be called MPC-P8 microprocessor board.

The P8 board contains an Onboard Menu Driving Diagnostics Tool coupled with a 2 x 16 alphanumeric display that allows full system reprogramming and diagnostics, four serial ports, a parallel port, an HSO high speed clocked serial port, and a real time clock. System ports are assigned as follows:

- COM1 (IBM) standard RS232 to drive IBM compatible systems
- COM2 (Duplex) duplex port for communication of duplex systems
- COM3 (PVF) communication with position velocity processor
- COM4 (Group) communication with the group G900 processor
- HSO Communication for Ez-LINK™ serial network system P8X microprocessor
- LPT1 (Dispatcher) parallel data communication with G900 processor, when P8 is used as Dispatcher processor

The P8 board is responsible for all the decision making for the elevator’s automatic mode of operation, and the monitoring of inputs and outputs for ASME-17.1A-2000 code compliance.

1.3.1.2 PIO9 (V900/ H900 Prodigy Controller Only)
The PIO9 board is universal to all Prodigy series of control systems, and is used in all types of elevators from hydraulic to traction. The PIO9 board utilizes high speed, microprocessor technology with a high level of system integration.

The PIO9 board contains: an Onboard Menu Driving Diagnostics Tool coupled with a 2 x 16 alphanumeric display that allows full system reprogramming and diagnostics, four serial ports, an HSO high speed clocked serial port, and a real time clock. System ports are assigned as follows:

- COM1 (IBM) standard RS232 to drive IBM compatible systems
- COM2 (Duplex) duplex port for communication of duplex systems
- COM3 (PVF) communication with position velocity processor
- COM4 (Group) communication with the group G900 processor
- TOC and HALL serial ports for Ez-LINK™ serial network

The PIO9 board is responsible for all the decision making for the elevator’s automatic mode of operation, and the monitoring of inputs and outputs for ASME-17.1A-2000 code compliance.
The PIO9 board absorbed several of the discrete boards used on the standard controller by utilizing surface mount technology and, by having fixture voltage fixed to 24 volts DC. The boards absorbed were P8, IO-7, IO-EX-B44, P8X, and one IO-EX board.

1.3.2 I/O-7 (V900/ H900 Standard Controller Only)
The I/O-7 is the main input-output board used in all the elevator standard control systems except for the group controller. It provides all of the main inputs and outputs required to run the elevator, such as safety inputs and door control signals. Such signals are permanently labeled on the left and right sides of the board.

The connector at the right top area of the board permanently contains the first 4 position indicators, direction arrows, fire buzzer and indicator outputs which drive the actual position and fire fixtures. Different types of IO-7 boards are provided, ranging from 110AC Standard to 24DC. When replacing this board, be sure that the type and voltage match the one being replaced, and that the LED power select jumpers are placed in the same positions.

1.3.3 IO-EX
The I/O-EX board provides all inputs and outputs that cannot be accommodated within the I/O-7 or PIO9 boards, including car calls, hall calls, hall gongs, position indicators, etc. Voltage and LED power select jumper positions are critical (as with the I/O-7 above) so care must be exercised when replacing this board. Note that the I/O-EX may not be present in all control panels.

1.3.4 IO-EX-B44-B (V900/H900 Standard Controller Only)
The I/O-EX-B44-B board provides ASME-17.1A-2000 redundancy inputs and outputs. Voltage and LED power select jumper positions are critical (as with the I/O-7 above) so care must be exercised when replacing this board. Note that the I/O-EX-B44-B may not be present in all standard control panels.

1.3.5 HLS-7
The HLS-7 board is the main relay panel board, housing all the relay logic to interface to the elevator system door control, starters, selector, etc. It should be noted that the HLS-7 does not contain any “Smart” logic. It is a basic board that has been developed to replace point-to-point wiring with a more cost effective and reliable solution. The HLS-7 is configured per job using onboard jumper configurations and relays types loaded for ND, BH, RUN and DPX.

1.3.6 Position and Velocity Control

1.3.6.1 PVF or Smart Drive Interface Board Version 3 (Sandwich)
The PVF or Smart Drive Interface version 3 system is made up of two boards as follows:

- a. The SDI MPU board, based on the Intel 80-196KB motion microprocessor, calculates all motion parameters for the position velocity feedback system. The SDI communicates with the P8 or PIO9 via a dedicated serial port through a 6-pin phone cable. All motion parameters reside in the SDI, including acceleration, deceleration, jerks, etc. The system calculates the optimum speed profile for each elevator trip, on
the fly, considering parameters, elevator position, demand, and instantaneous velocity.

b. The SDI I/O board is utilized by the SDI MPU board to support the onboard diagnostics and menu-driven reprogramming tool via a 20 x 2 LCD display unit. The SDI I/O enables the MPU to gather information from the elevator system including direction, elevator encoder count, selector, and slowdown signals.

The auxiliary safety microprocessor that monitors the elevator speed also resides on the SDI I/O board. It generates a second speed profile to prevent an overspeed condition at terminal landings or in leveling zones.

1.3.6.2 PVF or Smart Drive Interface Board Version 4 (Single)
The PVF or Smart Drive Interface Version 4 system is made up of a single board as follows:

a. The SDI MPU board, based on the Intel 80-196KB motion microprocessor, calculates all motion parameters for the position velocity feedback system. The SDI communicates with the P8 or PIO9 via a dedicated serial port through a 6-pin phone cable. All motion parameters reside in the SDI, including acceleration, deceleration, jerks, etc. The system calculates the optimum speed profile for each elevator trip, on the fly, considering parameters, elevator position, demand, and instantaneous velocity.

b. The SDI Version 4 supports the onboard diagnostics and menu-driven reprogramming tool via a 20 x 2 LCD display unit. The SDI Version 4 also contains the required IO to allow gathering of information from the elevator system including direction, elevator encoder count, selector, and slowdown signals.

The auxiliary safety microprocessor that monitors the elevator speed also resides on the SDI Version 4 board. It generates a second speed profile to prevent an overspeed condition at terminal landings or in leveling zones.

1.3.7 LSSM-5
The LSSM-5 board contains independently driven speed monitoring circuits required by elevator safety standards. These include overspeed, leveling speed monitoring, terminal slowdown speed monitoring, and inspection speed monitoring. The LSSM-5 accepts two types of feedback: (1) a DC tachometer feedback or, (2) pulses from a Hall Effect sensor working in conjunction with magnets surrounding the motor drive sheave.

NOTE: The COP, TOC boards are used when the elevator control system is designed with serial communications to the top of the car and the car operating panel. The Hall boards are used when the elevator control system is designed with serial communications to the hall stations. Skip 1.3.8 to 1.3.12 for standard or Prodigy non-serial elevator systems without “Ez-LINK.”
1.3.8 COP
The COP microprocessor board gathers all signals from the COP buttons such as car calls, door open and door close buttons, fire service, etc. and transmits such information via RS-485 to the TOC board. It also receives all output information for car call outputs, passing chime, fire indicators, etc. from the TOC through the same RS-485 communications channel.

The COP board serves as interconnection point for signals, that can’t be transmitted via serial communication, on their way to the traveling cable. Examples include emergency stop switch bypass, in car inspection, etc.

The COP board is linked to the TOC board via two twelve pin terminal connectors, housing all interconnects and shielded communication twisted pairs. When replacing the COP board, make sure that all board configuration jumpers are placed matching those on the board being replaced.

1.3.9 TOC
The TOC microprocessor board gathers all signals from the top of car including the selector unit, door operator limit switches, load weighing device, car top inspection station, etc. It also receives all information from the COP board front (and rear, if elevator has rear doors) via an RS-485 channel dedicated for communications between TOC and COP boards. This information is then combined with locally gathered information, and transmitted via RS-422 to the P8X board for standard controllers or to the PIO9 for Prodigy controllers.

The TOC board receives all output and control information from the P8X or PIO9 for door control and other information on its way to the COP board through the same RS-422 communications channel.

The TOC board serves as interconnection point for signals, that can’t be transmitted via serial communication, on their way to the traveling cable. Examples include emergency stop switch bypass, in car inspection, power supplies etc.

The TOC board is linked to the elevator controller via traveling cable. This cable contains three ten pin terminal connectors (which house all interconnects) and four sets of two twisted shielded pair two sets for communication and two sets for the selector DP1-DP2 signals.

When replacing the TOC board, make sure that all board configuration jumpers are placed matching those on the board being replaced.

1.3.10 COP-EX
The COP-EX board is a sixteen general input/output board that is used to accommodate signals not being housed by the COP or the TOC board such as car calls, attendant service, line per floor position indicators, etc.

When replacing the COP board, make sure that all board configuration jumpers are placed matching those on the board being replaced.

1.3.11 HALL
The HALL board is used at each landing in a multi-drop configuration. This board gathers hall call information, per opening, and transmits this information to the P8X or PIO9 board via RS-485 communication path. It also receives information that illuminates and extinguishes hall calls indicator lights and sounds hall gongs.

**CAUTION:** The HALL board is configured for a particular floor layout through SW1, an eight-switch pack (dip switch). When replacing the HALL board, make sure the dipswitch positions match those on the board being replaced, or permanent damage to one or more boards in the hall loop may occur.

### 1.3.12 P8X (V900/ H900 Standard Controller Only)

The P8X board is attached to the back of the P8 main elevator microprocessor. It communicates with the P8 via a high-speed port, HSO. The P8X function is to gather all information from the elevator serial network, from the COP-TOC, and hall station HALL boards, which is then conveyed to the elevator microprocessor. The P8X board also receives all process commands from the P8 board and distributes commands on the network, relieving the P8 microprocessor from any communications burden.

### 1.3.13 Power Supply

The power supply has a triple linear output +5VDC, +15VDC, and –15VDC. +5VDC is used for all microprocessor logic including P8, or PIO9, IO-6, IO-EX-B44-B, IO-EX, and PVF boards +15VDC and –15VDC are used to supply the PVF analog circuits used to generate the drive pattern control signal. Typical part: Power-One HBAA-40W-A W/OVP.

### 1.3.14 Power Supply Transformers

Power supply transformers are provided as necessary, according to the power requirements of each individual job, to step down and/or provide power isolation from the main power AC line.

### 1.3.15 Door Operator Interface Logic

Logic is provided as required for control of the various door operators and configurations used in the industry.

### 1.3.16 Fuses and Terminals

Fuses, terminals, and any miscellaneous job-specific circuits not part of the standard PC board set are provided as required for each specific job.

### 1.3.17 Motor Control Units

Elevator Controls utilizes several brands of DC-SCR and AC-Vector motor drives unit. Please refer to the manufacturer’s drive manual, provided with the controller information package, for details on the motor drive unit for each particular job.

**NOTE:** See 1.3.17.1 or 1.3.17.2 for the appropriate motor control information for your project.

### 1.3.17.1 SCR Motor Control & Starter Unit for DC Motors

The DC elevator motor drive consists of three distinct control components as follows:
a. The motor drive unit controls motor speed by applying a variable DC voltage to the motor armature and motor field. Input from a motor-shaft mounted encoder or tachometer unit provides closed loop feedback.

b. The motor contactor isolates the motor from the motor drive unit for safety in the event of a drive malfunction.

c. An optional drive isolation transformer and DC-choke filter. The transformer isolates the DC-SCR to prevent induced noise from affecting the building’s power supply. The DC-choke filters the current supplied to the motor armature by the DC-SCR drive to prevent audible noise from being generated.

1.3.17.2 AC Vector Motor Control & Starter Unit for AC Motors
The AC vector drive consists of three distinct control components as follows:

a. Regeneration circuits dissipate motor back-EMF to the line, for line regenerative drives, or to a bank of resistors (through a braking transistor) for non-regenerative drives.

b. The motor drive unit controls motor speed by changing the output motor voltage and frequency. Input from a motor-shaft mounted encoder unit provides closed loop feedback.

c. The motor contactor isolates the motor from the motor drive unit for safety in the event of a drive malfunction.
Section 2 – Preparation

2.1 General Information
This section contains important instructions and recommendations pertaining to the site selection environmental considerations, and wiring guidelines to ensure a successful installation.

2.2 Site Selection
While selecting the best location for the controller equipment take into account the following factors:

a. Make sure the control system is placed logically, while taking into consideration the rest of the equipment location.

b. Provide adequate working space for installation, wiring, and maintenance of the control system. Please note that rear access is not required on Elevator Controls standard control systems.

c. Do not install equipment in a hazardous location.

d. Do not install equipment in areas or on surfaces where it will be subject to vibration, the control systems contains parts such as relays that are placed in sockets whose functions may be affected by vibration.

e. Provide adequate lighting and working space for comfort and efficiency; a telephone line is desirable to provide access for optional remote diagnostics, as well as more efficient access to E.C.C. factory technical support if required.

2.3 Environmental Considerations
For proper operation and longevity, the elevator control system should be installed according to the following requirements:

a. The temperature inside the control system enclosure should be maintained between 32 to 104 degrees Fahrenheit (0 to 40 degrees Celsius). Higher or lower temperatures will reduce the life of the system and may prevent the system from functioning normally. Provide air-conditioning if required.

b. The air in the machine room should be free of corrosive gases. Air should be sufficiently dry to prevent condensation from moisture. NEMA 4 or NEMA 12 enclosures with integral air-conditioning units are available for these applications.

c. Avoid placing any control system cabinet or component near windows to prevent severe weather conditions from damaging the equipment.

d. Extreme levels of Radio Frequency (RF) radiation should be avoided. Radio Frequency Interference (RFI) may interfere with the operation of the control system. Elevator Controls hydraulic control systems have been tested by CKC Laboratories, Inc. Report Number IM00-029 and found to be in compliance with EN61000-4-2, EN61000-4-3 and EN61000-4-4 in accordance with EN12016 regulations.

NOTE: Hand-held communications devices used close to the system computers may generate disruptive RF interference.
2.4 Recommended Tools, Test Equipment and Manuals

The following tools are recommended for installation of V900-PVF control system:

a. Digital multi-meter
b. Assorted electronic tools such as pliers, cutters, flash light, Elevator Controls small screwdriver (supplied with each controller), etc
c. Amp-Prove probe-type ammeter
d. Telephone
e. Test weights
f. Control system “as built” wiring prints
g. This manual
h. Model V900/H900 Prodigy & Standard P8 Field Reprogramming manual
i. Motor Drive Control Manual (SCR or AC-Vector as required)
j. Oscilloscope and Meg-Ohm meter may be desirable for advanced troubleshooting (rarely required)
k. Tachometer to determine the elevator’s actual car speed
l. PVF Position and Velocity Feedback System Manual

2.5 Controller Installation Guidelines

NOTE: It is very important to follow control system wiring guidelines to prevent problems with interference and line pollution.

NOTE: Wiring to controller terminals must be done in a neat and careful manner. Stranded wire conductors must be twisted together to avoid strands that would create potential shorts if left out of terminals. All terminals and cable connectors must be checked for proper seating. When connecting flat cable connectors be certain to match pin #1 marks (arrow symbol on connectors, red stripe on cable) to prevent damage.

CAUTION: Restrict access to elevator control equipment and apparatus to qualified personnel only.

There are five different entry points that should be maintained separate while wiring the control system:

a. Power wiring: the line power coming from the elevator service disconnect with power ground.
b. Motor wiring: power to hoist motor, brake and ground.
c. Safety and Logic wiring: all wiring to fixtures and switches, as well as cross-connect signals from one car to another in a multi-car group system.
d. Communications cables: communication cables run from one controller to another in a group of two or more cars.
e. Encoder Feedback cables: cables used to deliver motor performance information from the encoder or Tachometer unit to the drive unit for speed control, and also to provide independent motor speed rotation feedback data to the Low Speed Monitor, LSSM-5, board.

⚠️ NOTE: Both encoder feedback and LSSM-5 feedback cables can be placed together in the same metal conduit.

☠️ WARNING: Do not connect the building power supply directly to the motor contactor, as this will damage power transistors in the drive unit.

איור נס要注意: Study your control system layout to achieve the best arrangement, keeping the five entry points separated and positioned logically to suit the particular control system you will be installing. Following are the proposed layout for wiring a standard and Prodigy controller.

איור נס要注意: The standard NEMA-1 enclosure provided for V900-PVF Standard & Prodigy controllers with factory knockouts, which suggest locations for wiring entry points. These knockouts are located as follows: one on the top right side of the enclosure for the communication cable; and three on each side of the lower portion of the enclosure for other required wiring.

Figure 2.2 – Typical V900 PVF Prodigy Controller Wiring Layout
Section 3 – Startup

3.1 General Information
Protect printed circuit boards from dust and foreign materials. Remove main fuses. Complete elevator controller mounting installation and wiring. Observe controller field terminal locations in relation to wiring ducts in order to determine optimum locations for wiring to enter the control equipment enclosure.

NOTE: The standard V900-PVF controller enclosure has several ¾” knockouts marked for wiring ducts which can be used as guides for location of knockouts required for each particular job.

CAUTION: Use care to protect circuit boards from metal debris when cutting.

CAUTION: Do not connect the building power supply to the motor contactor.

CAUTION: Power capacitors in the drive remain charged for some time after power is removed. Use caution to prevent shock injury.

3.2 Startup of V900 – PVF Microprocessor Control System

NOTE: These are not instructions for final adjustment.

In the following instructions it is assumed that all hatch doors are closed but not necessarily locked and all hoistway and machine room wiring is complete.

These instructions assume that the installer has a working knowledge of electrical troubleshooting. Follow prescribed procedures carefully.

If the elevator does not respond as expected, check the circuits according to your ability. If you can't locate the problem in a reasonable time, call in an adjuster or serviceman with advanced troubleshooting experience. Proceed with caution.

NOTE: You will find multiple LED indicators on PC boards and onboard computer diagnostics very useful tools that will save installation and troubleshooting time.

Read these instructions all the way through before starting work to become familiar with the entire procedure.

3.2.1 Test Ground Continuity
Test all terminals for continuity to ground. If continuity is identified, remedy the problem before proceeding.

NOTE: Terminal 3 is connected to ground and is used as system common.

3.2.2 Remove Group System Fuses (if applicable)
Make sure supervisory control system supply fuses are removed.
3.2.3  **Remove Primary Controller Fuses**
Remove fuses F4, F7, F8, FB1, and FB2 to disable primary controller relay voltage, brake control circuits, and the door operator. Place controller INSP and TEST switches in inspection and test positions, respectively (on).

**NOTE:** Always review prints to double check fuse designations and correct amperages, as well as to become familiar with job specific circuit requirements.

3.2.4  **Check Disconnect Switch**
Check the line side of the disconnect switch and verify all three legs are at the correct voltage.

**CAUTION:** Remove protective covering on PC boards and components before applying power.

**WARNING:** Make sure power is within 10% of specified control voltage or permanent damage could occur to both the motor drive unit and elevator control logic. Turn off the main line disconnect and correct any voltage problem before proceeding with installation.

3.2.5  **SH6 “Serial Safety” Jumper for Serial Link to Top of Car**

**NOTE:** If serial link to Top of Car is not used, skip to next step, 3.2.6.

Place the SH6 jumper on the HLS-7 board (which is located in front of the JDRK2 harness connector) to allow the safety string to be made without the TOC and COP boards being wired to the elevator system. This will permit car movement on Inspection mode; Refer to page 3 area 3 of job prints for reference on jumper function, which is to bypass the circuit that confirms that TOC and COP boards are in place.

3.2.6  **Turn on Main Line Disconnect**
Turn on the disconnect switch. For DC-SCR, check voltages at L1, L2, and L3 terminals located towards the top of the DC-SCR drive unit. For AC-Vector, check voltages at the Marathon terminal block or on the EMI-RFI filter input terminals, if job has been provided with such filters.

**NOTE:** For Prodigy controllers the drive unit and power terminals are located behind the front the panel, on the back panel.

3.2.7  **PVF System Setup**

3.2.7.1  **Verify PVF Parameters**
Read through the PVF manual and become familiar with the use of the PVF onboard diagnostics and reprogramming tool. Follow procedures described in 3.2.7 section to verify PVF parameter settings. Keep the PVF manual handy for reference start up, final adjust, and troubleshooting.
3.2.7.2 Initial Speed Parameter Guidelines
Familiarize yourself with the PVF Position and Velocity Feedback System Manual. The PVF computer system generates the speed pattern that is fed to the motor drive for speed control. The PVF system initial setup is done at the factory.

Verify initial parameter settings before attempting to run the car. See the PVF Manual Section 3, Program Variables, for a detailed explanation and description of the function of each parameter.

As a good rule of thumb, use speed divided by three to program all Jerks, Acceleration, and Deceleration parameters for jobs up to 300 feet per minute (i.e.: if the job is 300 feet per minute, program parameters to 100). For car speeds above 300 feet per minute, start with all parameters at 100 and tune as required for optimum performance during final adjustment of the elevator system. Also, confirm that inspection speed is set to a reasonable working speed (i.e. 20 to 50 feet per minute).

NOTE: DO NOT USE the "Quick Installation Reference Guide" in the PVF manual unless you're familiar with the Elevator Controls system or otherwise directed herein to do so. The guide in the PVF manual is intended for general reference purposes only, and as a quick reference when replacing PVF boards only, where no drive or controller parameter readjustment is required.

The following PVF parameters must be set correctly:
  a. Contract Speed (See PVF System Manual Section 3-3)
  b. Number of Floors (See PVF System Manual Section 3-4)
  c. Tach Polarity (See PVF System Manual Section 3-15)
  d. Tach Gain (See PVF System Manual Section 3-16). Final setting of this parameter requires the car to be running at contract speed.
  e. Tach Zero (See PVF System Manual Section 3-17)

3.2.7.3 Set Speed Pattern Clamps
The PVF pattern clamps must be set correctly. This is not a final adjustment. The speed clamp initial setup is done at the factory according to the values in the table below. Verify these preset values by accessing the PVF diagnostics submenu 2.5 “Set Speed Clamps”. Some clamps may not be used on your job; if your contract speed is less than the value shown below, that clamp parameter will not be used. Turn potentiometers for unused clamps fully counter-clockwise 20 turns. See PVF System Manual Section 3.6 for more details.

3.2.8 Index to Motor Drive Parameters Appendix

This section directs you to the appropriate appendix section of this manual for the various drive units utilized with the V900-PVF control system. Refer to the appendix section as it applies to your specific motor control unit as follows:

For example, if working with a Magnetek SCR drive system and a reference such as “Adjust the drive gain, refer to Section 3.2.8 entry x.1 of this manual to hold car…” is made in reference to Appendix B1 Section B1.1. If same reference is made for a Yaskawa F7 drive unit, it is referring to Appendix A1 section A1.1

3.2.8.1 Appendix A – AC Vector Motor Control Drives

A1 Yaskawa F7 drive unit  
A2 Magnetek HPV-900 drive unit  
A3 Magnetek HPV-600 drive Unit  
A4 KEB Combivert F5 drive Unit  

3.2.8.2 Appendix B – SCR Motor Control Drives

B1 Magnetek DSD-412 drive unit  
B2 Control Techniques Mentor II drive unit  

NOTE: Read through the Drive Manual section, “Drive Parameters Overview” pertaining to the appendix corresponding to the drive unit used in your particular installation before proceeding to Section 3.2.9.

Skip to Section 3.2.9 if not a KEB Combivert F5 Drive unit with Permanent Magnet Gearless motor elevator system application.

NOTE: KEB Combivert F5 Drive when used to drive Permanent Magnet Gearless motor elevator systems, the drive unit will have to learn the position of the encoder vs. motor every time the encoder is replaced, repositioned, or during start up to be able to generate proper motor torque control.

WARNING: Do not attempt to move the car before making sure all variables are set per actual motor requirements and section A4.2.2 of Appendix A4 has been successfully performed.

NOTE: Do not proceed further until step A4.2.2 of Appendix A4 has been successfully performed.
3.2.9 Verify Safety Switches

Verify that car, car-top stop and any other safety switches are set and operating properly. In order for the elevator monitoring system to permit movement of the elevator, the following conditions must be met:

a. Governor switch, governor contact must be wired between Terminals 4A and GOV.

b. The emergency stop switch must be wired between Terminals 4A and 17, and 17A to 17B for emergency stop switch monitor input, and the safety switches between Terminals 17 and 23. Refer to job prints page 3.

c. The PVF STO output will energize the SSAF relay if the PVF unit is in a normal mode of operation, no faults being detected.

d. The Motor Drive unit Drive On relay output should be on, completing the controller main safety string if the Motor Drive unit is in a normal mode of operation, no faults being detected.

e. The UP (Terminals 28 and 30) and DOWN (Terminals 29 and 33) normal limits must be made.

f. The car gate (Terminals 4 and CG) must be made, as well as the hoistway door safety string, bottom door locks (Terminals 4S and 19), intermediate door lock (Terminals 19 and 13), and top door lock (Terminals 13 and THD).

g. The Door Open Limit (Terminals 4 and DOLF) must be closed and the Door Close Limit (Terminals 4 and DCLF) must be opened. If equipped with selective rear doors, the rear Car Gate and Door Open and Close limits must follow the same status as the front limits.

h. The Emergency Brake “Rope Gripper” contacts, between Terminals BC1 and BC2, must be made to allow power to flow in the directional circuits (refer to job print areas 4 and 5).

i. Remove the SH2 jumper from the LSSM-5 board in order to bypass trip latching of the ST relay on the LSSM-5 speed monitor board during job installation.

j. If the controller is equipped with the Ez-LINK serial communication option, install the SH6 “SERIAL LINK” jumper on HLS-7 to enable safeties to set without the COP and TOC boards being installed.

⚠️ **NOTE:** Circuits above will allow the car to move on Car Top Inspection mode of operation.

⚠️ **NOTE:** In order to allow the car to be run on Controller Inspection, car top inspection, in-car inspection, and Access mode switches must be in the off position. Car Top Inspection (4 to ICTO), In Car Inspection (ICTO to ICIO), Access (INAC to INA0), and Hall & Car Door Bypass switches in controller must be on normal position.

⚠️ **NOTE:** If elevator installation does not require In Car Inspection or In Car Access, jumper the respective terminals above to permanently disable these functions.

3.2.10 Temporary Final Limit Jumper
If the car is at the top, or at the bottom of the hoistway, jumper the final limit terminals 17 and 23 to allow the car to move. **REMOVE THIS JUMPER AS SOON AS IT IS POSSIBLE TO DO SO.** Use the UP/DN rocker switch to control car movement.

**NOTE:** Local elevator safety code may not allow the use of a controller Inspection switch. In this case, the car top inspection station should be used to run the car.

If no relays are picked, check fuse F4 and verify that 110 VDC is present between Terminals 3 and 4A, and also between Terminal 4 and 3. If voltage is present on Terminal 4A but not on Terminal 4, turn to page 3 area 3 of the prints and verify the Emergency Stop and Elevator Safeties field wiring.

### 3.2.11 Running the Car on Inspection

#### 3.2.11.1 Signals Required for PVF to Generate a Pattern

The PVF computer receives commands from the elevator computer P8 or PIO9 board along with relay contact inputs to Terminals UP, DN, and enable on Terminal EX along with the inspection input INS.

**NOTE:** These inputs, connected via relay logic, are the minimum signals the PVF system needs to generate a pattern. These signals can be viewed at menus 3.4 and 3.6 on the PVF as shown:

<table>
<thead>
<tr>
<th><strong>3.4 CONTROL SIGNALS</strong></th>
<th><strong>3.6 EDGE I/O</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>UP = 0</td>
<td>EQS = 0</td>
</tr>
<tr>
<td>LU = 0</td>
<td>PEN = 0</td>
</tr>
<tr>
<td>DN = 0</td>
<td>MFW = 0</td>
</tr>
<tr>
<td>DZ = 1</td>
<td>ST = 1</td>
</tr>
<tr>
<td>INS = 1</td>
<td>EQ &amp; EQS =</td>
</tr>
</tbody>
</table>

0 = NOT ACTIVE   UP = UP DIRECTION   INS = INSPECTION INPUT
1 = ACTIVE       DN = DOWN DIRECTION  EQ & EQS = EARTHQUAKE INPUT

**NOTE:** ST indicates that PVF is ready and drives the SSAF relay in the safety circuit. The PVF system will not output a signal voltage until PEN (Pattern enable) is active at Terminal EX on the SDI top board. MFW (motor field weakening) is not used with AC Vector or SCR drives control systems.

If the ST, UP or DN, INS and PEN inputs are not active as you try to run the car in 3.2.11.3 below, then you will need to determine the cause. Problems most typically result from an open safety string, an open limit switch, or the drive unit not ready to run the hoist motor.

#### 3.2.11.2 Verify Safeties

Model V900-PVF Traction Controller Installation & Adjustment Manual 24
Verify that the main safety circuit SAF input LED is lit. This LED is located on the right side of the IO-7 board or PIO9. The IO7 board is located below the P8 microprocessor board for standard controllers. If the SAF LED is not on when the car is on inspection, trace the safety circuit, referring to job prints Page 3 area 3, to locate the problem.

**NOTE:** When no faults exist, the drive will normally pick the DSAF relay, and the PVF system will pick the SSAF relay.

### 3.2.11.3 Car Direction

**NOTE:** For KEB Combivert F5 Drive when used to drive Permanent Magnet Gearless motor elevator systems, Skip to section 3.2.11.4 below (3.2.11.3 has been verified as part of section 4.2.2 of Appendix 4).

Place the controller on inspection by placing the controller inspection switch in the inspection position. Run the car using the UP/DN switch on the controller. Car Top inspection, In Car Inspection and Access switches will need to be off in order for the controller UP/DN switch to work. If the car runs backwards, for AC-Vector control systems interchange two of the three motor leads from the bottom of the Delta contactor for SCR control systems interchange the two armature wires at the top of the Delta DC Contactor.

**NOTE:** Use care not to interchange the input power leads.

**NOTE:** If motor rotation is correct, verify that the motor does not produce unusual noise or vibration. Refer to the drive manual for details on Faults indications. If the pulse generating encoder direction is incorrect, the drive will typically trip, or the car will move very slowly or erratically, irrespective of the speed setting. Reverse the encoder direction by reversing encoder leads A and A/. If this doesn’t resolve the problem, check the encoder signal wiring.

**NOTE:** For Mentor II DC Drive if analog tachometer is use, feedback reversal fault will be generated as the car may momentarily try to run away before drive trip out occurs, reverse tachometer field wires to resolve problem.

### 3.2.11.4 Brake Adjustment

While attempting to run the car, adjust brake voltage to the desired value. Verify the actual brake data versus the controller data, referring to job prints page 4, area D3. If settings differ from actual measured values, call Elevator Controls for assistance in recalibrating brake circuits. Once settings and measured values agree, adjust brake picking and holding voltages to values required follow instructions found on prints Page 4, area D3.

**NOTE:** Brake power resistors are located inside the resistor cage on top of the controller.

### 3.2.11.5 Set Inspection Speed

Set inspection speed to zero using PVF parameter 1.12. Adjust the drive gain, referring to Section 3.2.8 entry x.1 of this manual, to hold the car at or near zero speed. Gradually increase inspection speed, using PVF program variable 1.12, to observe performance (do not exceed 100 FPM). A setting between 20 to 50 FPM is desirable during the installation phase.
Verify that the drive can follow the pattern signal as speed is increased, adjusting drive gain as needed. Refer to Section 3.2.8 entry x.1 of this manual.

NOTE: The higher the number entered as a response parameter, the more responsive the drive will be.

3.2.11.6 Brake Mechanical Operation
Prove that the brake will properly hold at least an empty car. Perform any necessary mechanical adjustments to obtain proper brake operation.

3.2.11.7 Car Speed Calibration
Run the car on inspection in the up direction. Measure car speed on the governor rope using a hand held tachometer.

Measured car speed should agree with the speed value setting. Adjust the motor speed, referring to Section 3.2.8 entry x.1 of this manual. This setting will be finalized when the car is run at full speed. Refer to the PVF System Manual Section 5, select display 3.1, Tracking Performance.

The Tach value displayed must match car speed. Adjust Tach Gain parameter 1.14 under PVF Program Variables menu. Refer to the PVF System Manual Section 3.16 for a more detailed discussion of the Tach Gain parameter.

NOTE: The higher the number entered as a Tach Gain parameter, the smaller the speed value displayed.

3.2.11.8 Verify Hoistway Clearances
Verify safety circuits between Terminals 4A and 23 and make any necessary corrections. Refer to page 3, area 3 of the job prints. Check the car top stop switch to enable/disable inspection up and down buttons. Inspect the full length of the hoistway to ensure the availability of required free running clearances. Check all door locks to ensure proper clearances have been maintained.

3.2.11.9 Verify Limit and Slowdown Switches
Check inspection access operation, (if provided); including proper operation of door lock bypass detection.

NOTE: The elevator safety code does not allow operation of the elevator on inspection access operation if the door locks are bypassed.

Be sure TM switches or slowdown limits, stop limits, and overtravel limits are all properly set according to the hoistway print.

3.2.11.10 Controller Connectors Seating
Verify that all connectors in the system are correctly seated. Ribbon and plug-in field wire connectors can wiggle loose when the system is being worked on. Press firmly on all connectors to seat them. Be sure duplex cables are installed along with any #18 wire cross
connections (if more than one car) according to the hoistway print. Install F50 fuse if used on this controller.

**CAUTION:** Proper seating and secure latching of all connectors is critical to reliable system operation.

### 3.2.12 Complete Installation

At this point the system startup is complete: the elevator car should run correctly on inspection. If you are still having problems, review the steps above and repeat as necessary. The elevator system installation should now be completed, including installation of the selector, etc.

Before running the system on automatic, follow steps 3.2.12.1 through 3.2.12.4, and complete steps described in Section 4 of this manual.

#### 3.2.12.1 Set Dead Zone

Verify and adjust (as required) the leveling switches on the car top for proper Door Zone dead zone, +/- 1/4". Correct vane lengths and switch arrangements are specified on job prints and selector reference materials.

**NOTE:** LU and LD, at Terminals 25 and 26 to Terminal 3 respectively, need to be off (0 VDC) when the car is at floor level.

Make sure all hoistway doors and car doors are closed and locked. Run the car on inspection mode through the entire hatch, making sure it is clear of obstructions.

#### 3.2.12.2 Position Feedback DP1 and DP2 Wiring

Use two twisted shielded pairs for the digital pulse output from the selector. Connect DP1 and DPC each to one wire in the first shielded pair. Connect DP2 and DPC each to one wire in the second shielded pair.

DP1 and DP2 are labeled the same on both the PVF-SDI board and the selector. DPC is labeled as DPC on the PVF-SDI board and DPC or MINUS (-) terminal on the selector side. See your drive PVF prints for a correct wiring schematic.

Be sure shields are connected at all intermediate junction terminal strips for continuity from the selector box to the PVF-SDI board EGND terminal. Be sure optical sensors on the selector are kept clean.

**NOTE:** Direct sunlight exposure (i.e.: in glass hoistway and other such applications) interferes with normal operation of the standard selector sensor head. Under these conditions, the optical sensor area must be shrouded in order to work correctly. Contact Elevator Controls technical support for guidance.

Test the DP1 and DP2 inputs to the PVF. Use Submenu 3.8 Target and Position. Run the car up on inspection; verify that the DP (digital pulse) value goes up and that it is positive. Run the car down on inspection; verify that the DP value goes down. If the DP value increments
in the wrong direction, or increases negatively when going up, reverse the DP1 in DP2 wire connections at the PVF-SDI top board.

3.2.12.3 PVF Learn Hoistway
The PVF system needs to learn the hoistway. Be sure normal stop switches do not open before car is fully level at terminal floors, and allow for approximately two (2) inches of overshoot in either direction.

This procedure is fully detailed in the PVF System Manual, Section 4.2 Set Up Mode. Note terminal post SH5, PVF LEARN JUMPER, has been provided on the HLS-7 relay board. Place this jumper to perform the set up procedure described below:

Set Up Mode:
1. Select menu 2, Hoistway, from the PVF diagnostics menu.
2. Select Entry 2.1 Set Up Mode.
3. Move the car down on Inspection Mode until it stops on the down normal limit switch, approximately 2 inches below the bottom landing.
4. Run the car up nonstop the full length of the hoistway, until it stops on the up normal limit switch, approximately 2 inches above the top landing.
5. Review the checklist below and Section 3.2.12.4 before removing the car from Inspection mode of operation.

Next, verify that the floor position table is correct. Use PVF System Submenu 2.2 Floor Position Table. Press the UP button on this menu, observing the recorded position for each floor. The floor positions are shown in two ways: feet (FT) and pulses (P). Each pulse represents about 3/16 inch. Floor position values should appear reasonable and correspond to what you would expect the floor heights to be. Any of the following indicate a problem.

- **Floor positions are not as expected.** Floor heights are measured relative to the bottom limit and should increase. If not as expected, check field wiring, especially DP1, DP2, DPC, EGND and door level switches. Be sure DP1 and DP2 shields are connected properly.

- **Floor positions decrease or are negative Pulse counts are less than 1000P.** Floor distance should start at 0 ft or 1000 pulses at the bottom limit and increase from there. If the count is negative, reverse DP1 and DP2 field wires, then go back to step 3.2.12.2.

- **Verify that the terminal slowdown position table is correct.** Use PVF System Submenu 2.3 Terminal Position Table. Press the UP button on this menu, observing the recorded positions for each terminal. Like the floor position table, these values should appear reasonable and correspond to what you would expect the terminal positions to be.

If you do experience a problem, check field wiring. Verify that the slowdowns are set in the correct positions, and that the car is allowed to overshoot the top and bottom floors by approximately two inches in each direction of travel.

3.2.12.4 Verify PVF Learn Procedure
To verify that the PVF learn procedure was successful, use following steps:

a. Using the PVF Menu 2 “HOISTWAY” Submenu 2.2 “Floor Position Table” verify proper floor heights. Refer to the PVF System Manual section 4.3.

b. Using the PVF Menu 2 “HOISTWAY” Submenu 2.3 “Terminal Position Table” verify learned positions for the terminal slowdown switches. Refer to the PVF System Manual section 4.4.

c. If proper floor heights and terminal slowdown switch positions appear reasonable, proceed to place the TEST switch to the ON position. This will put the system on Test mode when the INSP switch is turned OFF. TEST disables door opening (TEST mode does NOT disable door closing).

d. Remove the car from inspection, this will allow the car to re-level into the top floor if the learn hoistway procedure was successful. If the hoistway learn procedure was not successful, a “Hoistway Not Learned” error will be displayed on the PVF-SDI board LCD.

e. If a “Hoistway Not Learned” error message is generated, verify PVF parameters for contract speed 1.1, and number of floors 1.2, under Program Variables menu, verify selector and slowdown switch positions, then repeat step 3.2.12.3 until a successful hoistway learn is achieved.

f. **REMOVE THE PVF SH5 SDI LEARN JUMPER.**

g. On inspection mode, move the car below the floor onto the leveling vane, using the inspection UP/DN switch. Then place the INSP switch in the OFF position. The car should re-level up into the floor. Verify that the relays sequence properly for re-leveling. Adjust re-level speed, as required for accuracy and comfort, using PVF Program Variable 1.11. Repeat this step as required until re-leveling up is satisfactory.

h. Repeat step “g” above, this time starting with the car above the floor to verify and adjust re-level down.

[CAUTION: ] If you have not already done so, **REMOVE THE PVF SH5 SDI LEARN JUMPER** when you have completed this section.
Section 4 – Final Adjustment

4.1 Door Adjustment
The elevator should be shut down and main power shut off.

   a. Install door fuses F7 and F8.

   b. Position the car in the hoistway so that car doors can be adjusted to a preliminary
      setting.

   c. Open the doors by placing a jumper from the non-banded side of diode D73 (under
      the DO relay) to Terminal 3 on the controller and close doors by placing a jumper
      from the non-banded side of diode D65 under the DC relay to Terminal 3.

      Alternatively, place the car on inspection and follow door operation adjustment
      procedure described by the door operator manufacturer

☞ NOTE: Make sure jumpers on item c above are removed after door adjustment
      procedure is complete.

☞ NOTE: Most new solid-state door control systems offer adjustment procedures that
      require no interaction with the elevator controller.

4.2 Check Hoistway Clearances
The door operator must be operating properly with all door equipment clutches, rollers, etc.,
adjusted to correct running clearances. Make sure all hoistway and car doors in the building
are closed and locked.

Run the car on inspection the entire length of the hoistway to be sure that the hoistway is
completely clear of obstructions. Check to be sure that all selector vanes and the tape
selector unit are properly installed per manufacturer’s instructions.

4.3 Use of Test Switch
Turn the TEST switch to "Test" position, (the TEST switch is located on the HLS-7 board).
Placing this switch in the test position prevents the controller from opening the doors (both
front and rear if the car has rear doors) while car behaves as on Independent Service mode of
operation.

Verify that all ribbon cable connectors, harness connectors, and relays are seated properly.
Turn on AC power. Switch from inspection to normal operation. The car should travel to
the bottom terminal landing, or re-position itself to the correct landing.

☞ NOTE: If this does not happen, jumper terminal 4 to DC (door close button), place
the control test switch in the “TEST” position. Observe the LCD liquid crystal
display for Error Condition to determine why the elevator is not responding. Pay
particular attention to the multiple LED indicators on the I/O-7 or PIO9 board.

If the car is leveling, the LVL indicator will be off, and the car will not be able to respond
until the leveling process is complete. If any of the door opening devices or any call input is
active, the corresponding indicator will be lit. If the SD (or SU for up) indicator is on and
the Down relay is not picked, check the normal limit switch. Also, check the DSD2 and
USD2 LED’s. They must not both be off, or reversed, as these are the corresponding
terminal landing slowdown switches that open when the car is at each respective terminal
landing.

Refer to Troubleshooting Section 7 of this manual for guidance.

4.4 Ez-LINK Serial Communication System Verification

⚠️ CAUTION: Make sure the Serial Safety jumper has been removed from SH6 post
terminals on HLS-7 board, if job is equipped with Ez-Link to top of car.

✏️ NOTE: For non Ez-LINK systems, skip to Section 4.5.

4.4.1 Verify Communication to TOC Board
To verify communication to the top of the car, LED’s DIAG1 and DIAG2 on the TOC board
should be blinking (approximately 4 times a second). DIAG1 indicates communication with
the P8X or PIO9 board in the controller, and DIAG2 indicates communication with the COP
board (or boards if rear doors are present).

If the two diagnostic LED’s are not blinking 4 times a second, verify wiring, and shielded
communications wiring connections. Also, make sure all shields are correctly jumpered on
all hoistway junction terminal strips.

4.4.2 Verify Communication to COP Board
To verify communication to the COP board, LED’s DIAG1 and DIAG2 on the COP board
should be blinking (approximately 4 times a second). DIAG1 and DIAG2 indicate
communication with the TOC board on top of the elevator cab.

If the two diagnostic LED’s are not blinking 4 times a second, verify wiring. Perform this
same check for the rear COP board, if present.

4.4.3 Verify Communication from COP to TOC Boards
Verify all signals coming from the COP and TOC boards to the P8 or PIO9 elevator
microprocessor board. Refer to the Field Reprogramming Manual “Direct Access” menu.

To view the following table, have someone go inside the elevator cab and press each car call
and activate each button, while a second person selects and verifies proper activation
response in the P8 or PIO9 memory map below:

✏️ NOTE: Verify that all job-required signals activate the proper input memory location
in the P8 or PIO9 computer, per the table below, before removing the car from
Inspection operation. Table Fig 4.1 lists all possible signals. You need only verify
signals pertaining to your specific system.

To verify communications to the top of the car, LED’s DIAG1 and DIAG2, on the TOC
board should be blinking approximately 4 times a second. DIAG1 indicates communication
with the P8X or PIO9 board in the controller, and DIAG2 indicates communication with COP board (or boards if front and rear doors are present).

If either of the two diagnostics LED’s are not blinking approximately 4 times a second, verify wiring and communication shield connections. Also, make sure all shields are correctly jumpered on all hoistway junction terminal strips.

**ACCIF**: Front car call input

---

Model V900-PVF Traction Controller Installation & Adjustment Manual 32
4.5 Running the Car on Test Mode

⚠️ NOTE: When the test switch on the HLS board (located on the relay printed circuit board) is in the "TEST" position, the doors will not open when the car arrives at a floor.

⚠️ NOTE: To place car calls from the machine room for a standard non Ez-LINK systems, jumper from the IO-7 Call GND post, located on the top right corner of the board, to the car call field terminals on the IO-7 or IO-EX boards for standard controllers or from Terminal 3 to the car call field terminals on the PIO9 or IO-EX boards for Prodigy controllers.

⚠️ P8 or PIO9 with car program version V5.50 or latter, use the Reprogramming Manual to locate the car call entry menu by raising all four menu switches and pressing the UP or DN (down) buttons to display System Control. Lower the Menu / Sub switch to enter the System Control menu and press the UP button until EZ Link Advance is displayed. Lower the View / Edit switch to enter direction and floor data.

Procedure
- Place the car on test mode.
- Set the left LCD character to 1 to move the car up or 0 to move the car down by pressing the UP or DN buttons.
- Press the shift button SHIFT to move between characters.
- Set the right LCD character to the number of floors from the current position to move the car by pressing the UP or DN buttons. A valid floor offset entry is 1 to 9 where 1 will command a 1 floor run, and 3 will command a 3 floor run, etc.
- Press the write button WR to start. Keep pressing the write button each time the car arrives at a floor to continue moving the car up or down by the same number of floors.

If a car traveling in either direction fails to reach the call within a pre-determined interval, the controller will identify this occurrence as a fault condition and automatically stop the car.
Further operation of the elevator will be prevented until the fault condition has been cleared. To reset this fault, momentarily place the car on Inspection mode.

4.6 Speed Profile Adjustment
The speed profile reference drawing, Figure 4.6 below illustrates the parameters available for adjusting the elevator ride.

Figure 4.6 – Speed Profile

NOTE: Observing the pattern output and the tach signal from the drive can save a lot of time and hassle. The best way to accomplish this is with a dual-trace storage oscilloscope.

Connect one probe to the signal input terminals on the Motor Drive. This is the pattern signal, with a normal value range from 0 to +10 volts, with +10 volts being contract speed. Direction is determined by the UP or DN signal input.

Connect the second probe to the ABS Speed output. This is the Encoder feedback signal with a normal +10 to –10 volt signal output. Refer to page 4 of the prints for drive terminal designations.

CAUTION: If the grounding pin on your oscilloscope plug is electrically connected to the negative probe lead, then you MUST NOT attempt to connect the negative lead to the equipment or damage will occur. In this case, if your scope has 2-channels with channel B invert feature active, remove negative leads from probes, then press the A+B button on the scope. Use A and B probes to measure signals.
NOTE: After the speed pattern is adjusted as well as possible from the machine room, the adjuster should ride the car. A pair of hand-held radios and a helper can simplify this process, enabling the helper to adjust the system per the adjuster’s instructions from inside the car. There is simply no substitute for adjusting while riding the car.

With the car on Inspection, bring the car to the bottom floor. Remove the car from Inspection, leaving it on Test mode of operation. Place a car call for one floor above. The car should make a one floor run up from the first level and slowdown into the second floor. Observe how the system responds, especially the brake, motor and sheave. Make any necessary adjustments to the mechanical portion of the system. Problems with the brake or door clutch clearances will become apparent here. Correct any problems as they occur before continuing with this adjustment.

With the car on Test mode, make single and multiple floor runs, adjusting speed profile parameters as necessary to "mold" the speed curve. You will need to make a sufficient number of runs to be sure that the system responds as desired. Take your time; adjustment procedures are not inherently quick.

It is recommended that a series of test runs starting with one floor runs and then advancing to multiple floors runs up and down. If car vibration is detected, first check the encoder mounting and wiring. If mounting is solid and wiring is correct, adjust the drive response parameters as required, referring to Section 3.2.8 entry x.1 of this manual.

CAUTION: Higher drive gain numbers may cause oscillation, while lower numbers may cause sluggish response. Adjust these settings for optimal ride quality.

If the car will not move, refer to Section 7 of this manual for troubleshooting guidance. Note any error messages on the system LCD display. Look up these messages on Tables 7.2, 7.3 and/or 7.4, which describe problems and possible solution/s.

Pay particular attention to the multiple LED indicators on the I/O-7 or PIO9 board. If car is leveling, the LVL indicator will be off, and the car will not respond until the leveling process is complete. If none of the door opening devices or calls inputs is active, the corresponding indicator will be lit. If the SD (or SU for up) indicator is on and the Down relay is not picked, check the corresponding normal limit switch.

Also, check the DSD2 and USD2 LED’s. They must not both be off, or reversed, as these are the corresponding terminal landing slowdown switches that open when the car is at each respective terminal landing. Note any messages on the on the elevator computer board LCD display.

4.7 Final Ride Adjustment  (Read thoroughly before continuing)
4.7.1 Brake Tension and Drive Response Setup
With the car at the bottom landing, put the car on inspection and test weights equal to two-thirds of contract capacity in the car.

Next, start adding weights in 50 or 100 pounds increments, moving car on inspection UP and DN after each increase. Continue until the car is loaded to 125% of contract capacity.

Test brake tension to stop and hold 125% of a contract load by tripping any stop switch except car stop switch open while the car is running down on inspection. Hold the "DOWN" button in while you trip open the stop switch (preferably on the inspection station). The brake should stop the car.

Next, with the car still loaded at 125% of contract load, set Inspection speed = Leveling speed (approximately 4 FPM) and verify that the car lifts and lowers (moves both up and down the hoistway with this load) at approximately the same speed. If the car does not move in the up direction, increase the drive gain as needed, referring to Section 3.2.8 entry x.1 of this manual.

Finally, return inspection speed to the desired value once the procedure in this section is completed.

4.7.2 Contact Speed Vs. Pattern Adjustment
While making a long multi-floor run, verify that the car runs at contract speed when maximum (approximately 10) volts is applied to Motor Drive Pattern signal input terminals.

If not, adjust motor speed as needed, referring to Section 3.2.8 entry x.1 of this manual. Refer to the PVF System Manual Section 5, select display 3.1, Tracking Performance. The Tach display value must agree with car's speed. Adjust Tach Gain parameter 1.14 found in the PVF Program Variables menu, Refer to the PVF Manual Section 3.16 for a discussion of Tach Gain parameter adjustment.

NOTE: The higher the number entered in parameter 1.14 Tach Gain, the smaller the speed value displayed.

The car should now be running at contract speed with no overshoot on acceleration and deceleration into the floor. The idea is to get a smooth overall deceleration into the leveling zone, while minimizing time spent at a steady leveling speed.

4.7.3 Adjusting Speed Pattern and Performance
Adjusting the speed pattern can be more of an art than a science. You have two goals: ride comfort and brake-to-brake time. You will have to decide which to work on at any one time. The two goals are not exclusive; both can be achieved. The sections below provide the adjuster with information and hints to help fine-tune the elevator for best performance and comfort. Please read thoroughly, making adjustments as needed.

As you adjust the parameters described below, refer to the relevant sections in the PVF System Manual and/or the Drive Manual.
4.7.4 Decreasing Brake-to-Brake Time
   a. Increase Acceleration “Acceleration to speed”.

   **NOTE**: When you do this, you will probably have to increase Initial Jerk “Soft Start” and Roll Over Jerk “Round up to speed.” The jerk values should be larger than or equal to the Acceleration value. Example: if Acceleration is set to 100 FPM/s, Initial Jerk and Roll Over Jerk should be set between 100 FPM/s/s and 200 FPM/s/s.

   b. Increase Initial Jerk “Soft Start” and Roll Over Jerk “Round up to speed”.

   **NOTE**: Both of these parameters should be changed whenever “Acceleration to speed” is changed significantly. For quick brake-to-brake times, use 1.4 to 2 times the Acceleration value. Higher jerk values cause the pattern to reach contract speed faster.

   c. Increase Decel “Deceleration”.

   **NOTE**: Deceleration value is typically set from 25 to 50 FPM/s less than the Acceleration value. This improves passenger comfort and also makes final approach into the floor more accurate.

   d. Decrease Leveling Distance “Final approach”.

   **NOTE**: Within the PVF system, leveling distance is used in place of a final jerk rate. An oscilloscope can be very useful for viewing the shape of the final curve.

   **NOTE**: Leveling distance is measured in pulses generated by the landing system tape, 3/16 of an inch per pulse. Changes of at least six to ten pulses are required in order to see any change in performance. Leveling distance must always be greater than 16 pulses, which is only 3" of controlled floor targeting. Leveling distance should normally be greater than 32 pulses. A good working range is 38(P) to 62(P).

4.7.5 Improving Passenger Comfort
   a. Increase “Pattern Delay”. Refer to Section 3.8 in the PVF System Manual.

   **NOTE**: Increasing this setting is only useful if the car is pulling through the brake when the pattern starts. Increasing pattern delay produces a wait for a fixed user defined amount of time, allowing the brake to pick.

   b. Decrease “Leveling Speed”.

   **NOTE**: Leveling speed is typically set high at the factory, so the car will not stall coming into a floor. In most applications, leveling speed will need to be decreased, to about 4 to 6 FPM, in order to eliminate any bump felt when stopping.
c. Decrease Initial Jerk “Soft Start”.

NOTE: Excessively high jerk values can cause passenger discomfort.

NOTE: Some motors cannot follow high jerk values. The resulting overshoot can cause bumps during the ride. A dual trace storage oscilloscope can be used to determine whether the motor is the limiting factor. Connect the probe to the “Analog output 1” from the drive, then decrease the initial jerk setting until a smooth start can be seen when looking at the tachometer from the drive.

d. Decrease Roll Over Jerk “Round down to decel”. See part “c” above for hints on how to accomplish this by replacing Initial jerk with increased Roll over jerk.

e. Decrease Deceleration “Decel”.

NOTE: Excessively “Deceleration” values can cause passenger discomfort and can also cause the car to overshoot the floor.

Adjustment should now be completed. Verify and correct proper floor leveling, and make sure door zone sensors are adjusted to prevent door pre-opening beyond +/- 2” from floor level.

NOTE: If you change any door zone or floor sensor, the PVF system will need to relearn the hoistway.

CAUTION: Verify that all connectors in the system are correctly seated, if you have not done so before. Ribbon and pluggable field wire connector can wiggle loose while the system is being worked on. Press firmly on all connectors to ensure that they are seated securely.

4.7.6 Speed Clamps Final Adjustment

After all ride adjustments described above are complete, the pattern clamps must be adjusted.

While still on TEST mode, run the car to the bottom floor. Then make one complete run of the hoistway up to the top terminal landing. Next, run down to the bottom terminal in one run.

Access the PVF System Submenu 2.5 Set Speed Clamps. The system will display proper values for final speed clamp and potentiometer settings.

NOTE: These values will now be different than the initial values. Use the displayed value for T1 through T14. Press the UP button on the PVF system and repeat for the next clamp. Continue until all clamps are adjusted.

NOTE: If you change any velocity pattern variables in the PVF, the speed clamps may need to be readjusted. Repeat speed clamp adjustment any time you adjust Initial Jerk, Acceleration, Roll-Over Jerk, Deceleration Jerk, Deceleration or Leveling Distance.

4.7.7 Landing System Vanes
Verify placement and operation of vanes and switches for proper position indicator stepping. Verify operation of all call buttons, and all functions including fire service main, alternate and phase 2, independent and access operation of the car, door devices and switches, terminal slowdowns, normal and limit switches, as well as all safety switches, etc. Verify and correct floor leveling as required.

4.8 Motor Limit Timer Control
If the car is traveling in either direction and fails to reach the call within a pre-determined time interval, the controller will identify this occurrence as a fault condition and automatically stop the car. To reset a motor limit timer fault, cycle the inspection switch or power disconnect.

LED indicators will show the computer error code while the LCD display will indicate the corresponding error status. The motor limit timer is factory preset for 180 seconds. Refer to the Model V900/H900 Field Reprogramming Manual for timer adjustment instructions.

4.9 Multiple Door Open Times
The V900 PVF controller is equipped with selective door timing for car, hall, and short door open times. The factory-preset values are field adjustable using the onboard diagnostics unit. Refer to the Field Reprogramming Manual for complete details. Check door open times for proper operation conforming to ADA and other applicable codes.

NOTE: The hall door timer starts as soon as the car engages DZ, even if it is still leveling. If the pre-opening option is not set, doors may not finish opening before the hall door timer expires. If this happens, because the car takes too long to finish leveling into the floor, extend the hall door timer value to allow for the extra leveling time required.
Section 5 – LSSM-5 Adjustment

5.1 LSSM-5 Functional Description

The LSSM-5 or Low Speed Safety Monitor board is an independent means for monitoring elevator safeties and performance. In case of an elevator speed malfunction, the LSSM-5 will latch, preventing movement of the elevator until board latching circuits are reset by pressing the RESET button on the board.

Movement of the elevator is prevented by removing power from the ST relay coil, which in turns prevents the AA relay from closing which prevents the Delta starter from energizing.

The ST relay is also monitored to confirm proper operation before car motion is enabled.

NOTE: The Low Speed Safety Monitor (LSSM-5) contains several circuits required by ASME-17.1A/ASME A17.1 code, as well as other safety circuits. Therefore, it should be adjusted with care to ensure the integrity of the safety monitoring system.

The LSSM-5 system monitors:

a. Elevator overspeed
b. LSSM tachometer monitor
c. Leveling and inspection overspeed
d. Terminal slowdown monitor
e. Runaway elevator condition.

CAUTION: The following adjustments should not be attempted until final adjustment of the car is complete. If these adjustments are made prematurely, this procedure will have to be repeated after final adjustment.

CAUTION: TP-8 is ground. All measurements are to be made with the negative meter lead attached to TP-8. Do not use any other ground point for this purpose. If an oscilloscope is used, be certain that the ground lead is isolated from the line or board damage will result.

CAUTION: Verify that jumper SH2 on the LSSM-5 board has been removed. Be sure to REPLACE THE SH2 JUMPER once adjustment is completed. The SH1 jumper enables an external reset input to the LSSM-5 board. If this option is not currently being used, be sure the SH1 is not loaded.

NOTE: Section 5.2 is for Pulse Input feedback and Section 5.3 is for Tachometer feedback. Proceed to the appropriate section.
5.2 Setup Utilizing Pulse Input
Place the SH3 jumper on the LSSM board in the “FREQ” position. Place the “TEST” switch on the HLS (relay) board in the TEST position these will disable door open operation and hall calls. Make a multi-floor run so that the car achieves contract speed. Measure and record the highest voltage on test post TP-6 with respect to test post TP-8 on the LSSM-5 board.

NOTE: Skip to Section 5.4 to continue LSSM-5 adjustment.

5.3 Setup Utilizing Tachometer Input
Place the SH3 jumper on the LSSM-5 board in the “VOLTAGE” position and confirm that resistor R45 is installed. Place the “TEST” switch on the HLS (relay) board in the TEST position these will disable door open operation and hall Calls. Make a multi-floor run so that the car achieves contract speed while adjusting Tach Gain potentiometer so that the voltage on terminal TP-6 with respect to terminal TP-8 on the LSSM-5 board is 8 volts.

5.4 LSSM-5 Adjustment Procedures

5.4.1 Overspeed
Set the overspeed potentiometer by running the car at contract speed and turning the "OVERSPEED" potentiometer counter-clockwise until the board indicates an overspeed trip. The "OVERSPEED" and the "SAFETY TRIPPED" LED’s should be lit. This procedure verifies that the overspeed circuit is working.

Multiply the tach voltage, recorded from Section 5.2, or the 8 volts setting from Section 5.3 above, by 1.15. Set the "OVERSPEED" potentiometer so that this voltage is read between TP-3 and TP-8. This procedure sets the overspeed trip point to 115% of maximum normal speed.

5.4.2.1 Tach Loss
Set the Motor Drive unit to activate the output tied to the LSSM board's "ABS" input at 10% of contract speed, refer to section 3.2.8 section x.2 Digital Outputs for parameter setting. While making one floor runs, slowly turn the "TACH LOSS" potentiometer clockwise until the board indicates a tach loss trip. This verifies that the LSSM tach loss circuit is working.

Multiply the voltage recorded from 5.2, or the 8 volts setting from Section 5.3 above by 0.03. Set the "TACH LOSS" potentiometer so that this voltage is read between TP-1 and TP-8. Make several runs to verify that no tach loss tripping occurs. If it does occur turn "TACH LOSS" potentiometer counter clockwise by one eight of a turn at a time while incrementing the motor drive unit “AS” output setting by 5% at the time, refer to Section 3.8 of this manual for “AS” parameter number direction. Call elevator Controls if condition persists after four increment steps.

5.4.2.2 Leveling & Inspection Overspeed
Set the leveling and inspection potentiometer with the car on inspection. While running the car, turn the "LEV/INSP" potentiometer counter-clockwise until the board indicates leveling and inspection trips. The "LEV/INSP" and the "SAFETY TRIPPED" LED’s should be lit. This verifies that the leveling and inspection overspeed circuit is working.
Multiply the voltage from 5.2 or the 8 volts setting from Section 5.3 above by 140 then divide this number by the contract speed of the elevator in feet per minute. This is the recommended tach voltage at 140 fpm. Set the "LEV/INSP" potentiometer so that this voltage is read between TP-4 and TP-8. This sets the leveling and inspection speed trip point to 140 fpm.

**EXAMPLE:**
- Contract speed = 400 fpm
- Tach Voltage @ contract speed = 5.00 V
- \( 5.00 \times 140 = 700 \); \( 700 \div 400 = 1.75 \) (the answer)
- Set the voltage between terminals TP-4 and TP-8 to 1.75 V

### 5.4.2.3 Terminal Slowdown

Verify from controller prints if the "SLDN" terminal on the LSSM board is tied to the 4A bus. If it is, skip this adjustment.

Otherwise, while making multi-floor runs into either of the terminal landings, turn the "SLOWDOWN" potentiometer counter-clockwise until the board indicates a slowdown trip as the car slows down approaching the terminal. Now turn the potentiometer clockwise, a half turn at a time, until no trip is indicated on terminal slowdown.

Measure the voltage between terminals TP-2 and TP-8. Turn the "SLOWDOWN" potentiometer until it rises 0.1 V.

**EXAMPLE:**
- If the 'non-tripping' voltage at TP-2 is 6.50 V, set it to 6.60 V. Then make multi-floor runs into both terminal landings to confirm that the board does not indicate a slowdown trip. If a trip is detected, increase the voltage at between terminals TP-2 and TP-8 in 0.1 V steps until no trip is indicated. Finally, check to see that the voltage setting between terminals TP-2 and TP-8 is less than or equal to the voltage recorded from 5.2 or the 8 volts setting from Section 5.3 above.

### 5.4.3 Runaway

This function is not presently being used. Verify the potentiometer setting to 20 turns clockwise, producing 11 volts between terminals TP-9 and TP-8.

**NOTE:** Reinstall jumper SH2 on the LSSM-5 board. Adjustment in this section is now complete.

**NOTE:** The LSSM-5 board has two fault indications. If a momentary fault occurs the associated LED will illuminate and stay lit as a warning. The safety circuit will not open unless a fault is maintained for at least 0.4 seconds, which will be indicated by illumination of the Safety Trip LED.
Section 6 – Elevator Safety Tests & Inspection

6.1 Performing Elevator Safety Tests & Inspections

NOTE: The following procedure is intended as a guide while performing periodic inspection and safety tests of the elevator system. Please refer to the Safety Code for Elevators and all applicable local codes for specific requirements.

WARNING: Safety tests should be performed by a qualified adjuster or service personnel. A helper should always be present and prepared to turn off the main line disconnect to remove power from the elevator if needed when the car is run with safety switches bypassed. Proceed with caution.

NOTE: For the following safety tests, 6.2 thru 6.5, remove the wire from terminal RD, if absolute floor position is provided on the elevator controller, or program FC86 bit 1 to 0 (if the controller is equipped with Ez-LINK serial communication). Refer to the Model V900/H900 V5.x Field Reprogramming Manual, “Direct Access” operation, to disable the Absolute Floor Encoding option if it is being used.

RECONNECT THE WIRE REMOVED FROM TERMINAL RD OR PROGRAM FC86 BIT 1 TO 1 WHEN SAFETY TESTS ARE COMPLETED.

6.2 Car Buffer Test – Fully Loaded Car

NOTE: For two stops elevators refer to Appendix B3 of this manual to perform test.

a. Place a full load in the car; place the controller test switch in the test position.

b. Enter a call to a floor several floors up from the bottom landing (but not to the top floor).

c. Jumper terminal 4A to all down slowdown switches terminals (DSD1, DSD2, and DT6 thru DT14 to bypass all present down slowdown switches as required.

d. Identify and remove signal wires DP1 and DP2 from SDI top board DP1 and DP2 terminals.

e. Place the controller inspection switch in the inspection position, and run the car one or more floors down to a lower floor level. Be sure the DZ relay is picked. Reconnect the DP1 and DP2 wires and place the controller inspection switch in the normal position.

f. Place a jumper from controller terminals 17 to 23 to bypass safety switches. Place a jumper from controller terminals 29 to 33 to bypass the down normal limit switch.

g. Enter a car call to the bottom floor to run car into the buffer. After the car strikes the buffer, and drive sheave slips under the cables, quickly flip the controller inspection switch to the inspection position to stop the car. Run the car up to the bottom landing door zone area and REMOVE ALL JUMPERS PLACED IN THE PROCEDURE DESCRIBED ABOVE.
NOTE: The SDI microprocessor board will open the safety string after detecting the pulse count failure caused by the buffer test. Reset the SDI after the buffer test is completed and the car is stopped to restore safety circuits to normal operation.

6.3 Counterweight Buffer Test – Empty Car

NOTE: For two stops elevators refer to Appendix B3 of this manual to perform test.

a. Place the controller test switch in the test position.

b. Enter a call to a floor several floors below the top landing (but not to the bottom floor).

c. Jumper terminal 4A to all up slowdown switches terminals (USD1, USD2, and UT6 thru UT14 to bypass all present up slowdown switches as required.

d. Identify and remove signal wires DP1 and DP2 from SDI top board DP1 and DP2 terminals.

e. Place the controller inspection switch in the inspection position, and run the car one or more floors up to a higher floor level. Be sure the DZ relay is picked. Reconnect the DP1 and DP2 wires and place the controller inspection switch in the normal position.

f. Place a jumper from controller terminals 17 to 23 to bypass safety switches. Place a jumper from controller terminals 28 to 30 to bypass the up normal limit.

g. Enter a car call to the top landing to run the counterweight into the buffer. After the counterweight strikes the buffer, and drive the sheave slips under the cables, quickly flip the controller inspection switch to the inspection position to stop the car. Run car down to the top landing door zone area and REMOVE ALL JUMPERS PLACED IN THE PROCEDURE DESCRIBED ABOVE.

NOTE: The SDI microprocessor board will open the safety string after detecting the pulse count failure caused by the buffer test. Reset the SDI after the buffer test is completed and the car is stopped to restore safety circuits to normal operation.

6.4 Governor & Rope Brake Test (ASME A17.1-2000 Section 2.19.1)

a. Place a jumper from controller terminals 17 to 23 to bypass safety switches.

b. Manually trip the governor overspeed switch and verify that the following events occur: GTS and GTSX relays drop out; the Emergency Brake or “Rope Gripper” sets; the GTSM LED monitor is illuminated; and the P8 or PIO9 board LCD displays a Governor Contact Fault.

c. Lift the governor cable off the governor, and then spin the governor while measuring its speed to verify electrical and mechanical tripping speeds. A variable speed drill motor is a good method for spinning the governor.

d. Replace the governor cable and return the governor overspeed switch to the normal position.

e. Repeat procedure 6.4.c for a counterweight governor, if any.
f. **REMOVE JUMPER** between terminals 17 and 23, and verify that the SAF input LED on IO-7 or PIO9 is not lit.

g. Press the “ANSI-RST” button on HLS-7 board. The Rope Brake and the GTS and GTSX relays should pick, the GTSM LED monitor should be off, and the SAF LED should be on.

### 6.5 Safety Overspeed Test – Fully Loaded Car

a. Put a full load in the car then place the controller test switch in the test position.

b. Enter a call to the top floor.

c. Place a jumper from controller terminals 17 to 23 to bypass safety switches. Place a jumper between terminals 4A and GOV to bypass the governor.

d. Set the required parameters to run the motor at 1.4 times the contract speed (refer to Section 3.2.8 entry x.3 of this manual). Return the car to the top landing door zone area and return the inspection switch to the normal position.

e. Enter a car call to the bottom landing after preparing to measure car speed at the trip point. The car will accelerate to overspeed at which time the safeties will set firmly. Immediately flip the controller inspection switch to the inspection position to stop the car. Restore the car safety contacts to normal and the governor contact to normal. Return the parameter for motor speed to its original value. **REMOVE JUMPER** between terminals 4A and GOV.

f. Repeat the procedure described in this section for a counterweight safety test, if required causing an empty car to overspeed from the bottom landing up.

h. **REMOVE JUMPER** from terminals 17 to 23.

⚠️ **NOTE**: The SDI microprocessor board, LSSM-5 board and/or the motor drive may open the safety string after detecting the failure caused by the overspeed test above. Reset the SDI, LSSM-5 or Drive unit after the overspeed test is completed and the car is stopped to restore safety circuits to normal operation.

### 6.6 Terminal Stopping Devices

#### 6.6.1 Terminal Stopping Devices Test (ASME A17.1-2000, Section 2.25)

**Down Direction**:

a. Place the car on inspection, as the stopping devices function identically in both inspection and automatic operation.

b. Place a jumper from controller terminals 17 to 23 to bypass the safety switches.

c. Run the car down past the bottom landing. The car should stop when the down Normal Stopping Device (NTSD) contact is opened.

d. Run the car up. The car should move up, allowing the NTSD contact to close.
Up Direction:

e. Run the car up past the top landing. The car should stop when the up Normal Stopping Device (NTSD) contact is opened.

f. Run the car down. The car should move down, allowing the NTSD contact to close.

g. **REMOVE JUMPER** from terminals 17 to 23.

6.6.2 Final Terminal Stopping Device Test (ASME A17.1-2000, Section 2.25.3)

Down Direction:

a. Remove the jumper between controller terminals 17 and 23. Place a jumper from terminals 29 to 33 to bypass the down NTSD.

b. Run the car down, past the bottom landing. The car should stop when the Final Stopping device (FTSD) contact is opened.

c. Attempt to run the car. It should not move in either direction. Verify that the safety string is open by confirming 0 volts from terminal 23 to terminal 3.

d. Place a jumper between controller terminals 17 and 23.

e. Remove jumper from terminals 29 to 33. Verify that the NTSD is still open by confirming 0 volts from terminal 33 to terminal 3, and that the car will not move in the down direction.

f. Replace the jumper from controller terminals 29 to 33. Run the car down until the buffer is fully compressed. Verify that the FTSD remains actuated by removing the jumper from terminals 17 to 23 and confirming 0 volts on terminal 23 to terminal 3.

g. **REPLACE JUMPER** between terminals 17 and 23, and **REMOVE JUMPER** between terminals 29 and 33.

h. Move the car up to the bottom landing door zone area, then **REMOVE JUMPER** between terminals 29 and 33.

Up Direction:

a. Run the car to top landing.

b. Remove the jumper between controller terminals 17 and 23. Place a jumper from terminals 28 to 30 to bypass the down NTSD.

c. Run the car up, past the top landing. The car should stop when the Final Stopping device (FTSD) contact is opened.

d. Attempt to run the car. It should not move in either direction. Verify that the safety string is open by confirming 0 volts from terminal 23 to terminal 3.

e. Place a jumper between controller terminals 17 and 23.

f. Remove jumper from terminals 28 to 30. Verify that the NTSD is still open by confirming 0 volts from terminal 30 to terminal 3, and that the car will not move in the up direction.

g. Replace the jumper from controller terminals 28 to 30. Run the car up until the buffer is fully compressed. Verify that the FTSD remains actuated by removing the
jumper from terminals 17 to 23 and confirming 0 volts from terminal 23 to terminal 3.

h. **REPLACE JUMPER** between terminals 17 and 23, then **REMOVE JUMPER** between terminals 28 and 30.

i. Move the car down to top landing door zone area and **REMOVE JUMPER** between terminals 17 to 23.

### 6.6.3 Emergency Terminal Stopping Test

#### NOTE: This test procedure requires that the LSSM-5 monitor board has been adjusted per section 5 of this manual.

#### NOTE: The LSSM-5 Slowdown input “SLDN” has been provided Plug in jumper labeled D55 on the HLS-7 board to be used while performing this procedure, located towards the left center top of the HLS-7 board below the JLS harness connector.

To verify operation of the Terminal stopping perform following steps:

a. Place the car on Test mode of operation.

b. Place a car call to execute a multi floor run.

c. When the car reaches contract speed unplug the “D55” Plug in jumper, to simulate the opening of the NTSD device, The LSSM-5 board will trip with a Slowdown trip LED indication.

d. The car should come to a stop and no further car movement will be allowed.

e. Plug back in the “D55” Plug in jumper and verify the car will not be allowed to move.

f. Reset the LSSM-5 board to restore elevator service, repeat test for opposite direction.

### 6.7 Emergency Terminal Speed Limiting Device Test (ASME A17.1-2000, Section 2.25.4.1)

#### Down Direction:

a. Enter a call to a floor several floors above the bottom landing (but not to the top floor). Place a jumper from controller terminals 28 to 30 and 29 to 33 to disable the NTSD. Remove the SH2 jumper from the LSSM-5 board.

b. Identify and remove signal wires DP1 and DP2 from SDI top board DP1 and DP2 terminals.

c. Place the controller inspection switch in the inspection position, and run the car one or more floors down to a lower floor level. Be sure DZ relay is picked. Reconnect the DP1 and DP2 wires, and place the controller inspection switch in the normal position.

d. Enter a car call to the bottom floor. As the car approaches the bottom landing, the SDI microprocessor should initiate an emergency slowdown upon detection of the opening of the down slowdown switches after detecting interruption of normal floor
counts as caused by steps “a” and “c” above. Verify that the car has stopped and that motor and brake contactors are not energized.

f. Verify that the car safeties have not been applied.

**CAUTION:** After completing safety tests, be sure to **REMOVE JUMPERS** above, and **REPLACE** the SH2 jumper on the LSSM-5 board.

**Up Direction:**

a. Enter a call to a floor several floors below the top landing (but not to the bottom floor). Place a jumper from controller terminals 28 to 30 and 29 to 33 to disable the NTSD. Remove the SH2 jumper from the LSSM-5 board.

b. Identify and remove signal wires DP1 and DP2 from SDI top board DP1 and DP2 terminals.

c. Place the controller inspection switch in the inspection position, and run the car one or more floors up to an upper floor level. Be sure DZ relay is picked. Reconnect the DP1 and DP2 wires, and place the controller inspection switch in the normal position.

d. Enter a car call to the top floor. As the car approaches the top landing, the SDI microprocessor should initiate an emergency slowdown upon detection of the opening of the up slowdown switches after detecting interruption of normal floor counts as caused by steps “a” and “c” above. Verify that the car has stopped and that motor and brake contactors are not energized.

e. Verify that the car safeties have not been applied.

**CAUTION:** After completing safety tests, be sure to **REMOVE JUMPERS** above, and **REPLACE** the SH2 jumper on the LSSM-5 board.

**NOTE:** An Emergency Terminal Speed Limiting Device Test (ASME A17.1-2000, Section 2.25.4.2) is not required on elevators that have an emergency terminal speed limiting device that complies with ASME A17.1-2000 Section 2.25.4.1

**NOTE:** **RECONNECT THE WIRE REMOVED FROM TERMINAL RD OR PROGRAM FC86 BIT 1 TO 1 WHEN SAFETY TESTS ARE COMPLETED**, if Absolute Floor Encoding is used.

**6.8 Test Procedures for Compliance: Monitoring Critical Circuits**

(ASME 17.1-2000 Sections 2.26.9.3 and 2.26.9.4)

**6.8.1 This Section Describes Test Procedures that Confirm Compliance with Part B, Redundancy & Monitoring in Critical Circuits**

(ASME A17.1-2000, Sections 2.29.9.3 and 2.26.9.4)

**NOTE:** All relays used as critical components are **Safety Relay SR6**, such relays are known as forced guided relays with the characteristics which allow the
monitoring of one contact to be used to determine the state of the remaining relay contacts.

NOTE: LCD refers to the P8 or PIO9 display unit for all tests below, unless otherwise specified

NOTE: Make sure elevator is placed on TEST mode of operation and elevator cab has been evacuated before proceeding with testing procedure below.

6.8.1.1 Microprocessor Monitoring

Critical Component: P8 or PIO9 Microprocessor
Redundant Component: P8 or PIO9 and GTS watch dog timers
Monitored Component: Memory Checksum, I/O Integrity check

The P8 or PIO9 microprocessor board incorporates a watch dog timer which needs to be refreshed by the program loop every 0.25 seconds, a second watch dog timer is used to time out the P8 main safety output for the GTS relays, therefore in the event that the computer were to malfunction the watch dog timer will perform a computer reset and in the event that the computer is not able to reset, the GTS watch dog timer will reset the GTS output, to disable the GTS relays and removing power to Starter coils.

GTS Watch dog timer test:
Press the reset button on the P8 or PIO9 and hold it down to prevent the computer from functioning. This will also prevent the onboard microprocessor timeout from updating the GTS output. As a result, GTS relay should drop; resetting the GTS relay outputs opens the power circuit to the Starter coils.
Print reference to GTS and GTSX contacts 4 is page 1 area 1 of the prints.
To restore, release pressure on the reset button.

P8 or PIO9 Watch dog timer test:
Turn power off and remove program chip labeled L.Hex, turn power back on and observe the Power on LED on the P8 board blink at the rate of 0.25 seconds demonstrating the effect of the P8 or PIO9 watch dog timer, turn power off to restore program chip.

NOTE: The P8 or PIO9 also performs a memory integrity check for by writing a pattern to the Ram memory and by performing check sums to the program portion of the software and comparing them to default stored values, if the program gets corrupted the computer will display a “Memory Corruption Error” and will disable all outputs.

P8 I/O Integrity Check (Standard controller only)
Turn power off and remove the ribbon cable that connects the P8 to the Monitor board, this should signal the computer that the computer I/O string to the monitor board has failed. The computer display should show, “Safety String Open,” preventing the computer from executing any motion commands.
Restore the ribbon cable into its socket. Make sure socket latching hooks are latched.
NOTE: The IO-EX-B44 circuits are part of the PIO9 board.

6.8.1.2 GTS & GTSX Relay Operation and Monitoring
Critical Component: GTS and GTSX Relays
Redundant Component: GTSM Computer Monitoring Input
Monitored Component: GTS and GTSX Relays contacts

Apply 110 VDC using a jumper from terminal 4A to R13 resistor, located above the HDR
relay label, on HLS-7 board. The LCD should show, “GTS Relay Fault”. GTS and GTSX
relays should drop, Confirm that the car will not respond to hall or car calls. The latching
fault should not clear until the ANSI-RST button is pressed.

6.8.1.3 Stop Relay Proper Operation and Monitoring
Critical Component: STOP Relay
Redundant Component: STOPM Computer Monitoring Input
Monitored Component: STOP Relay Contacts

Apply 110 VDC using a jumper from terminal 4A to harness connector JSDI-6, STOPM
monitor input, located on the top left corner of the HLS-7 board. The LCD should show,
“Stop Relay Fault.” Confirm that the car will not respond to hall or car calls. REMOVE
JUMPER. Car shall return to normal operation once jumper has been removed.

6.8.1.4 DZ Relay Proper Operation and Monitoring
Critical Component: DZ Relay
Redundant Component: DZM Computer Monitoring Input
Monitored Component: DZ Relay Contacts

On inspection move the car outside door zone area, remove field wire from terminal DZM on
HLS-7 board, remove car from inspection. The LCD should show, “Door zone relay fault.”
Confirm that the car will not respond to hall or car calls. Replace wire into DZM terminal
to return Car to normal operation.

6.8.1.5 Leveling Relay Operation and Monitoring
Critical Component: LVL Relay
Redundant Component: LVLM Computer Monitoring Input
Monitored Component: LVL Relay Contacts

Position the car below or above floor level using Controller Inspection mode, Short resistor
R4 to terminal 4A, R4 is located on HLS-7 board below JUP ribbon cable connector. Turn
Controller Inspection switch off. The LCD Display should show, “Level Relay Fault.”
Confirm that the car will not respond to hall or car calls. REMOVE JUMPER. Car shall
return to normal operation once jumper has been removed and ANSI-Reset push button is
pressed.

6.8.1.6 Car Gate Relay Operation and Monitoring
Critical Component: CG Relay
Redundant Component: DLM Computer Monitoring Input
Monitored Component: CG Relay contact.
With the car doors fully closed, DLK LED indicator on IO-7 or PIO9, DCLF LED indicator
OFF, apply 110 VDC with a jumper from terminal 4A to terminal SH47 jumper, located
above HDR relay label, on HLS-7 board. The LCD should show, “Door Lock Relays Fault.”
Confirm that the car will not respond to hall or car calls. REMOVE JUMPER car shall
return to normal operation once jumper has been removed.

6.8.1.7 Car Stop Bypass Relay Operation and Monitoring

Critical Component: CSB Relay

Redundant Component: CSBM Computer Monitoring Input

Monitored Component: CSB Relay contact.

With the car level at a floor, remove field wire from terminal 17B on the HLS-7 board, to
remove power to CSBM computer input. The LCD should show, “Car stop bypass relay
Fault” Confirm that the car will not respond to hall or car calls. Replace wire to terminal 17B
to return car to normal operation.

6.8.1.8 Entry purposely left blank

6.8.1.9 Entry purposely left blank

6.8.1.10 Delta and BK2 Contactors, Motor and Brake Contactor Monitoring

Critical Component: AA Relay, Delta and BK2 contactors

Redundant Component: STPM Computer Monitoring Input

Monitored Component: AA relay, Delta and BK2 Auxiliary contacts.

With the car level at a floor, remove AA relay from its socket on the HLS-7 board, to remove
power to STPM computer input. The LCD should show, “Contactor Drop relay Fault”
Confirm that the car will not respond to hall or car calls. Replace AA relay Car shall return
to normal operation once relay has been replaced. Repeat for Delta and BK2 contactors by
manually pressing contactor instead of removing wiring from auxiliary contacts.

6.8.1.11 Entry purposely left blank

6.8.1.12 LVLO Relay output Operation and Monitoring

Critical Component: LU and LD Selector signals

Redundant Component: LVLO Computer output & LVL relay.

Monitored Component: LU & LD, LVLM input.

Place car on test mode of operation and make several one and multi floor runs, observe that
the LVLO output LED on IO-7 or PIO9 board and that the LVL Relay energizes only when
the car comes into leveling zone of target floor independently of the LU and LD inputs.
Please refer to test 4 above for LVL Relay test for LVL relay test.
6.8.1.13 DZ1 and DZ2 Selector signals Operation and Monitoring

**Critical Component:** DZ1 and DZ2 Selector signals  
**Redundant Component:** DZI, DZM Computer inputs and DZ relay.  
**Monitored Component:** DZ relay and DZI, DZM computer inputs.

Place car on test mode of operation and make several one and multi floor runs, observe that the DZ input t LED on IO-7 or PIO9 board come on and the DZM input goes off as the car passes over the trucking zone but the car continues to move in high speed only allowing leveling and door operation at the target floor. Refer to test 3 above for DZ relay test and unintended movement test below for further monitoring of the DZ1 and DZ2 inputs.

6.8.1.14 Hall & Car Door Bypass Switch Operation and Monitoring

**Critical Component:** Hall and Car Door Bypass Switches  
**Redundant Component:** HDBM Computer Monitoring Input  
**Monitored Component:** Hall and Car Door Bypass Switches Contacts

Jump R15 resistor top to ground, R15 is located above the STOP relay on HLS board. The LCD should show, “Door Bypass System Fault.” Confirm that the car will not respond to hall or car calls. **REMOVE JUMPER.** Car shall return to normal operation once jumper has been removed.

Place the car on Automatic Operation and open the hall and/or car doors, the DLK LED should be off. Turn on Car Door Bypass and/or Hall Door Bypass switch(s) as necessary. Verify that the controller mode of operation changes to Inspection.

On the controller relay board, flip the Inspection Switch to “INSP.” Flip the run switch “Up” and then “Down” and confirm that the car will not run on inspection. Turn on Car Door Bypass and/or Hall Door Bypass switch(s) off, to return car to normal operation, and press the ANSI-Reset push button to return car to normal operation.

**NOTE:** If the hoistway door or car door is bypassed, the elevator controller will prevent the car from being run using the machine room inspection circuit or on access inspection mode, the car will only be allowed to move on Car Top Inspection mode of operation.

6.8.1.15 Detection of Jumpers on Door Safety String

**Critical Component:** Car Gate and Hoistway Door Locks  
**Redundant Component:** CG Relay  
**Monitored Component:** CG, THD, DLK and DCL Computer Monitoring Input

With the car on automatic operation, place a jumper from terminal 4 to CG on the HLS-7 board. Press the Door Open button and allow doors to fully open. The LCD should show, “Door lock system fault.” Confirm that the car will not respond to hall or car calls. **REMOVE JUMPER.** Car shall return to normal operation once jumper has been removed.

With the car on Automatic Operation, place a jumper from terminal 4 to THD on the HLS-7 board. Press the Door Open button and allow doors to fully open. The LCD should show, “Door Lock System Fault.” Confirm that the car will not respond to hall or car calls. **REMOVE JUMPER.** Car shall return to normal operation once jumper has been removed.
Place the car on Inspection Mode and verify that the car will not respond to hall or car calls.

6.8.1.16 Door Open and Closed Simultaneously

**Critical Component:** Door Opened & Door Closed Limits
**Redundant Component:** DOL and DCL Computer Monitoring Inputs
**Monitored Component:** Door Opened & Door Closed Limits

Place a jumper from the Terminal DOB to terminal 4 on the IO-7 or PIO9 board and allow the doors to open fully. Confirm that the DOLF LED indicator on the IO-7 or PIO9 board is off, and remove the DCLF input wire from IO-7 or PIO9. The LCD should show, “Front Door Limit Switches Fault.” Confirm that the car will not respond to hall or car calls. **REMOVE JUMPER** and reattach DCLF input wire to return car to normal operation.

6.8.1.17 Revert to Automatic Operation (ASME 2.26.9.3.d)

**Critical Component:** IN Computer Input, SU or SD Computer Outputs
**Redundant Component:** IN, and STOP relays
**Monitored Component:** INM, and STOPM Computer Monitoring Inputs

With the car on Inspection operation, place a jumper from D20 or D26 diode anodes on the HLS-7 board to terminal 3 “ground.” These diodes are in series with the computer SU and SD direction relay outputs. Confirm that the car will not move and will not respond to any car or hall call demand.

**REMOVE JUMPER.** Return the car to Normal mode of operation.

6.8.1.18 Unintended Movement (ASME 2.19.2)

**Critical Component:** DZ, and LVL Relays
**Redundant Component:** DZ, and LVL Contacts
**Monitored Component:** DZM, LVLM, CG, and THD Computer Monitoring Inputs

Place a jumper from the Terminal DOBF to terminal 4 on the IO-7 or PIO9 board and allow the doors to open fully. Confirm that the DOLF LED indicator on the IO-7 or PIO9 board is off. Turn power off, remove wires from 27 and DZM terminals located on HLS-7 board. Restore power.

The LCD should show, “Unintended Movement System Fault.” Relays GTS and GTSX should drop, setting the emergency brake and opening the directional circuits. Turn power off and rewire terminals 27 and DZM. Confirm that the error does not reset by cycling power. The latching fault should not clear until the ANSI-RST button is pressed.
6.8.1.19  Single Ground
Critical Component: N/A
Redundant Component: N/A
Monitored Component: N/A

Short terminal 4 located on the controller power terminal strip, (not on the any of the PC boards) to ground. Fuse F4 should blow removing power to all elevator control relay logic disabling all controller functions. Turn power off, and replace fuse.

6.8.1.20  Permit Car Speeds Over 150 fpm (ASME 2.26.9.3.c except 2.26.1.5.10(b))
Critical Component: LVL, STOP Relay, Motor Drive
Redundant Component: LSSM-5 Board, ST Relay
Monitored Component: LVL, STOP Relay Contacts

Place the car on Inspection operation. View the PVF parameters menu and select the inspection speed parameter. Write down the current inspection speed (so it can be restored later). Then increase inspection speed to 150 fpm. Run the car on Inspection and verify that the LSSM-5 board trips on Leveling/Inspection. It should produce a LEV/INSP fault. This prevents the ST relay from picking which in turn should prevent the AA relay from picking and the motor contactor from operating. Refer to Section 5, LSSM-5 in this manual for LSSM-5 adjustment.

Reset the LSSM-5 board and restore the inspection speed to the original setting.
Section 7 – Troubleshooting

7.1 System Not Functional in General (Car Won't Run)

NOTE: The Solid State portion of the Elevator Controls Microprocessor Controller is the most reliable part of the entire elevator system. While it is possible that a problem may occur, one should first look to the power controller and "outside world" for the malfunctions that most frequently take elevators out of service.

NOTE: Earthquake faults can only be cleared by placing car on controller Inspection operation, once earthquake switches and sensors have been reset, then returning the car to Normal operation.

7.1.2 General Troubleshooting Tips.

For your convenience, and in order to save troubleshooting time, the V900-PVF controller is equipped with multiple indicators that are designed to help you troubleshoot at a glance.

You are strongly advised to pay particular attention to the indicators on the I/O or PIO9 board. Every action instructed by the computer is indicated (DOF for example means door open function, the computer wants to open doors), and every action the human interface wants the computer to perform is also indicated (DOB for example means the door open button is active).

NOTE: Signal names written with bar on top of the signal name, indicates the signal is in active mode when the LED is off (FRS and FRA are a good examples – when the LED is off they indicate the car is on main or alternate fire mode respectively).

The computer error code LED display will flash a particular status/error code as detected by the P8 or PIO9 computer; a list of these codes can be found permanently applied to the inside of the controller door. Extra or replacement copies can be made from the list found in the Field Reprogramming Manual.

Computer error/status codes are also displayed in English format on the LCD display. Finally, an optional PC may be used for powerful troubleshooting, diagnostics, and for monitoring purposes.

7.1.3 Car Not Running General Check List

a. Make sure that the car is not on Fire Emergency Service; The P8 or PIO9 will display the fire operation active if any. During normal operation of fire emergency circuits, 24-110V should be present on each fire recall terminal with respect to terminal 3, (refer to prints page 5 for fire interface circuits).

b. If all terminals for Fire Emergency Service are properly set, refer to Section 7.2.1 for directions to reset the different modes of Fire Emergency Service.
c. If the elevator is not set to Fire Emergency Service, all power supplies should then be checked. The natural starting point is the three-phase input. There must be 208-480 VAC (as specified) present between all combinations of phases.

d. Verify that each power control step-down transformer has the correct secondary voltage (refer to Controller Schematic page 1 for terminal and fuse numbers). Replace fuses as necessary.

e. Terminal 4A should measure approximately +110 VDC. The voltage at Terminal 50, (hall lamp supply) with reference to ground and the voltage between Terminal Strip terminals 1 and 2 should be measured and verified to be in accordance with the voltages shown on page 1 of the job prints. If any of the above power supply voltages are not within range, check the appropriate fuses.

NOTE: System common is the 3 buss, (normally terminal 3 is connected to chassis ground) unless otherwise noted all DC voltage measurements are with respect to Terminal 3 or chassis ground.

f. Verify the Safety String (schematic for it is located on the upper portion of page 3 of the job prints). The Safety String is made up of normally closed safety contacts and switches connecting Terminal 4A to Terminal 23. In order for the car to run, all of these contacts must be closed, which will cause +110 VDC to be applied to Terminal 23 signaling the computer input that the safety string is closed (SAF input is active, verify LED on IO-7 or PIO9).

g. Assuming Terminal 4 is operating properly at +110 VDC; verify that the computer display does not show Safety String Open. If this message is displayed, check to be sure that the termination jumper plug has been correctly placed on the last IO or IO-EX board; inside the Out ribbon cable connector.

h. Verifying that the GTS indicator located on the IO-7 or PIO9 is on, the following relays should also be on: GTS, GTSX, and STOP (STOP will be on for Automatic mode of operation and off for Inspection/Access operation) CG, and once demand is establish, U or D (depending on intended direction). AA should be on, H relay will also pick if the slowdown for that direction of travel is closed and automatic mode of operation is selected.

NOTE: All relays mentioned below on item “i” are located on the HLS-7 board.

i. Direction (SU/SD) and speed signal HR both enter the HLS-7 board from the computer relay driver outputs on the I/O-7 or PIO9 board via the connecting ribbon cable. Pin numbers are indicated on prints (pin one is indicated by a red conductor in the ribbon cable). If a high speed run toward a call is required, register a call and check the appropriate up or down arrow (SUA/SDA) LED. If neither arrow is on, make sure no special function has control of the car (INS in, INA out), and that the fire warning indicator (FWI) is off. If all the above functions are normal, call registration should establish a direction of travel as indicated by an arrow, which can be observed on the IO-7 top right corner or towards bottom left corner on the PIO9 LED indicator. If no arrow is displayed, refer to the Microprocessor Troubleshooting Section 7.6 following below.
j. Some of the relay coils referenced above are hardware interlocked through the door safety circuit. In order for the car to move away from a landing, all doors must be closed and locked. A locked condition is indicated by a lit DLK indicator on the I/O or PIO9 board (+110 VDC on Terminal 11). An unlocked condition leaves the DLK indicator unlit (with 0 VDC on Terminal 11). Also the door closed limit switch should be open and the door open limit should be made, (verify 0 volts on terminal DCL and +110 VDC on terminal DOL). If the door string indicates an unlocked condition, examine and repair door locks as required.

k. Should the U or D relays remain unlatched with a properly locked door circuit, check the UP STOP LIMIT switch located between terminals 28 to 30, similarly terminals 29 to 33 for down. These switches are feeding power to the directional circuits. If switches are not made, the direction relays can not be energized by the microprocessor outputs. See page 3, area 4 of prints for stop limit switches and directional circuit functions.

7.2  Microprocessor Error Reporting and Correction

7.2.1 Elevator Normal Operation Fault Monitoring and Display
The table below shows the different faults that can be generated from the normal monitoring portion of the system as follows:

Scrolling Message: Indicates the display shown on the LCD display for each fault.

Description and Possible Solution: Explains how the fault was generated and possible

🌿 NOTE: Faults listed in Figure 7.2 below will not prevent the car from starting or executing the function fault such as Fire Service, Independent Service, Etc. Faults listed in Figure 7.2 will prevent the car from running.

🌿 NOTE: A group of special conditions are recognized by the microprocessor. If one of these "errors" occurs, a code will be displayed corresponding to that condition. The microprocessor will scroll up to 6 errors at a time on the LCD display. The eight LED array will display the error that needs too be corrected first, that is, the one with the highest priority.

🌿 NOTE: The field technician should look first to the LED array to identify the error that needs to be corrected first. Error codes can be found in this Section (below) and on the inside of the control equipment enclosure door.

7.2.2 ASME-17.1A fault Monitoring
The table below shows the different faults that can be generated from the ASME-17.1A monitoring portion of the system as follows:

a. Message: Indicates the display shown on the LCD display for each fault.

b. Output: The response of the system by dropping Stop relay only, or Stop and GTS-GTX combination depending on the severity of the fault.

c. Reset Required Yes: Indicates that in order for the car to return to normal the fault generating problem has to be resolved and the ANSI-Reset push button has to be pressed to clear the fault. Reset Required No: will allow the car to return to normal operation as soon as the problem causing is resolved.

d. Conditions Producing Monitor Fault: Indicate the input and output flags that are involved to generate such faults.

e. Description and Possible Solution: Explains how the fault was generated and what may be a corrective action to resolve fault.

f. Address of Bit in Memory: Indicates where in memory the computer stores the state of the monitored points, please refer to the Field Reprogramming Manual to see how to access these memory locations.

7.2.3 ASME-17.1A Fault Monitoring Flow Charts
The following section contains a series of flow charts showing the different scenarios that create an ASME-17.1A monitoring fault. Flow chart analysis may aid understanding of system processes in order to resolve problems that may occur with the elevator control system.

Space intentionally left blank

7.2.3.1 Unintended Movement Flow Chart
The following flow chart shows the status and events that result in Unintended Movement Fault.
7.2.3.2 ASME-17.1A Monitoring Analysis Input Fault Flow Chart

The following flow chart shows the fault-scan process for logging and responding when an ASME-17.1A monitoring fault is detected.

Start AnalyzeInputs

SAF = On
Main safeties are closed

Is there a fault already logged in?

Yes
No

Start AnalyzeInputs

Is there a fault already logged in?

Yes

Set flags to indicate rest of program no faults

No

Check status of unintended movement fault

ckMovement

Yes

Copy current fault number to monitorErr for fault tracking and display

No

Check all other ansi monitored faults such as relay faults, door lock monitoring faults, Contactor faults, etc.

Set flags to indicate program what action to take based on fault priorit. i.e. Drop GTS relays, or hold car once doors open, etc.

No

Any fault present

Yes

Copy fault to EEPROM for tracking

No

Preset search engine with no faults to start process

End analyzeInputs
7.2.3.3 ASME-17.1A Fault Reset Process Flow Chart
The following flow chart shows the fault reset process required by the monitoring programs for both latching faults (faults requiring the reset fault input) and not-latching faults (faults which the program will auto reset once the fault condition clears).
### 7.3 Malfunctions in the Operating System

#### 7.3.1 Doors Operating Improperly or Not at All

<table>
<thead>
<tr>

</table>

7.3.3 Position Indicator Malfunctions

<table>
<thead>
<tr>
<th>Problem</th>
<th>Solution</th>
</tr>
</thead>
<tbody>
<tr>
<td>Position indicator is out of step with the elevator car physical position</td>
<td>The computer system contains automatic synchronizing logic to place the position indicator in step with the car whenever it reaches a terminal landing. Therefore placing a call for a terminal landing should resynchronize the position indicator.</td>
</tr>
<tr>
<td></td>
<td>Should the car get out of step repeatedly, or the position indicator jumps from terminal to terminal, a stepping problem in indicated. Verify proper operation of the DZ, STU, STD (and ISTU and ISTD, if provided) inputs, making sure that the proper signal LED operates when magnetic switch is on a vane (note that STU/STD, ISTU/ISTD indicators go off when input is active), and signal reaches the appropriate controller input terminal.</td>
</tr>
<tr>
<td></td>
<td>Also check for missing or damaged hoistway vanes, and make sure that activation of STU or STD does not overlap with activation of DZ or LU/LD.</td>
</tr>
</tbody>
</table>

7.4 Proper Stepping Sequence
This section is intended to describe the state of the stepping signals required to execute an automatic run, and to illustrate how the elevator computer, P8 or PIO9, keeps track of the car movements as it travels from floor to floor.

### 7.4.1 Initial Selector Status
While the Car is at a landing floor level
1. The DZ indicator LED will be lit, indicating car is at floor level.
2. STU/STD signals (at P8 or PIO9 board memory location F000) from the PVF system are lit inside computer memory; Refer to the Field Reprogramming Manual “Memory Flags List” menu.
3. Indicating that stepping inputs from SDI are not active, i.e. they are active low.

### 7.4.2 Re-Arming the Selector
1. As car travels out of the door zone area, the DZ indicator should turn off.
2. The STU (or STD for down) indicator will turn off as the SDI sends stepping signals to the P8 or PIO9 microprocessor Position indicator output will reflects the new floor position.
3. Further activation of STU/STD will be ignored until after ISTU/ISTD is cycled (on/off), "re-arming" the electronic selector for stepping at the next floor.

### 7.4.3 Car Approaching a Stop at Floor
1. Once the PVF system determines that the travel distance to the target floor has been met, it sends the last STU/STD signal to the P8 or PIO9 board, causing the elevator microprocessor to update position to match the target position.
2. After the last STU/STD signal, the P8 or PIO9 drops the H relay output.
3. The PVF will hold the last ISTU/ISTD until the car passes the position half way in between floor preceding the target and the target.
4. After the last ISTU/ISTD signal, the P8 or PIO9 to drops the HI flag and turns on LVLO output to enable the leveling sequence.
5. As the car travels into the Door Zone area, it is driven into final stopping position by the LU and/or LD leveling sensors.

### 7.5 Microprocessor Troubleshooting
This section is intended to help determine if the Computer Logic Check indicates a faulty board, and if so, which if any of the microprocessor system logic boards is bad so that a good board can be substituted. No attempt has been made to diagnose specific problems that might occur on any particular board, since doing so requires specialized test equipment, which is not generally available to elevator service mechanics in the field.

Assume it has been determined that an output signal is not being sent by the computer system when conditions indicate that a signal should be present. The next step is to determine
whether the computer is attempting to turn on the output or not, and if not, what might be preventing it from doing so.

To find out what the computer is trying to do or "thinking", look into the computer memory itself using the onboard diagnostics described in the Field Reprogramming Manual.

7.5.1 Troubleshooting Example

For example, let’s say you note that the door open output fails to operate door open relay DO in response to a door opening input signal. You observe that the DOF (door open function) output LED indicator does not turn on. Set the diagnostics switches as described in the Field Reprogramming Manual. Locate the DOF function on the Memory Flags Listing page, which indicates an address of F007 for DOF. Check the LED indicator corresponding to address location F007 and observe that the LED is off.

This tells us the computer is not turning on the Door Open output. This must mean that either the open signal input (say door open button DOBF address F001 is not coming in, or the computer incorrectly thinks doors are already fully open (DOLF - door open limit front input is zero, address F000). Alternatively, the computer may have determined it unsafe to open doors (DZ=0 or HIR=1). Inspection of these flags will show that either (1) an input was not supplied to the system properly, or (2) that the computer cannot see it. In the later case, it is suspected that the I/O7 or PIO9 board (especially if DOBF and DOLF do not track input signals) or ribbon cable connecting the I/O board to the computer board is faulty for standard controllers.

Based on the methods used in this example, any other input/output can be traced to the computer memory to help identify the cause of the fault. The section following illustrates the computer logic used to process the indicated outputs and signals.

7.6 Operational Logic Description

The following description of computer logic control is described in a synthesized format (Boolean logic flow equations). They are very simple to read and understand if the following guidelines are understood:

a. The logic equations below use signal abbreviations, as listed in the Field Reprogramming Manual, which are referenced in the job prints describing input/output signals. Straightforward signal abbreviations aid understanding (e.g., DOB=door open button, DC=Down Call cancel, etc.).

b. The small zero superscript used on a signal name indicates that the signal is active when off, or it is otherwise required that the signal go off in order for something else to happen. Thus, DOLF⁰ is a signal that, when on, indicates that doors are not fully open. When off, DOLF⁵ indicates that doors are fully open.

c. The plus symbol + is used to indicate an OR function. Thus, the equation: DOB+SE reads, “either door open button input OR safety edge input". Likewise, the & symbol is used to indicate an AND function. Thus the equation DOI & DOLF⁰=DOF reads, "door open intent on AND door open limit off will generate a door open function output". Please note that the words AND and OR are used instead of & and + symbols when combining two smaller equations.
7.6.1 **Door Open Function Output - DOF**

(Demand) CCF + UC + DC  OR (Input) DOB + SE + PHE + DHLD  AND DZ = DOI

DOI & DOLF$^0$ = DOF

7.6.2 **Door Open Function Rear Output - DOFR**

SAME AS ABOVE, FLAGS ARE SUFFixed WITH LETTER R: CCFR, UCR, ETC.

7.6.3 **Computer Up Output - SU**

Start: DZ & DLK$^0$ & HIR & DMU & DCL$^0$ = SU

Hold: HIR + DZ$^0$ AND SU & DLK$^0$ = SU

7.6.4 **Computer Down Output - SD**

Same as SU above, replace DMU/SU with DMD/SD.

NOTE: DMU/DMD are the demand flags, they are set any time the computer is requested to move the car in response to a call (SUA+SDA = 1), car lost (BFD+TFD =1), parking demand (UPF+LPF = 1), fire or emergency recall (FRM+EPR).

7.6.5 **High Speed Output - HR**

Start: DLK$^0$ & EQA$^0$ & (DMU & USD1 + DMD & DSD1) & LVL & DOI$^0$ = HR

Drop: CCT + HCT + CCF + CCR = HR$^0$. Call answered.

OR DMU$^0$ & DMD$^0$ & (SU & STU + SD & STD) = HR$^0$. Lost demand.

OR DLK + EQA + (DNS & DSD1$^0$) + (UPS & USD1$^0$) = HR$^0$. Not save for HR.

7.6.6 **Call Disconnect and Reject - CCD, HCDX, HCR**

A. CCD - CAR CALL DISCONNECT (CAR CALLS WON'T LATCH):

IN + EPI + FRM + EPS + EQA + MLT + INC + ISR$^0$ + TFD + BFD + CCDFU + CCDFD = CCD

B. HCDX - HALL CALL DISCONNECT (HALL CALLS WON'T LATCH):

FRS$^0$ + FRA$^0$ + EQA$^0$ = HCDX. If duplex both cars’ flags are considered.

C. HCR - HALL CALL REJECT (CALLS LATCH BUT CAR WON'T RESPOND):

INC + FRM + EQA + TOS + ISR$^0$ + HLW + SAF$^0$ + IN + EPS = HCR

NOTE: Even if HCR=0 (CCD=0), Hall (car) calls will be ignored by computer (even when latched-in if car stopping table indicates car should not respond to such call. See Car Stopping table in field re-programming manual.

7.7 **PVF troubleshooting.**

Refer to the PVF System Manual, Sections 7 and 8, for troubleshooting this microprocessor. It will helpful to read through the PVF manual to become aware of the application of this microprocessor and to learn how to use the onboard diagnostics tool provided as an integral part of this board.

WARNING: Do NOT depress the PVF microprocessor reset button while car is running, as it will cause an emergency stop. Use extreme care.
7.8 Hardware Logic

7.8.1 Computer Power Supply
The proper voltage to the computer board is +5VDC +/-5%; this voltage should be checked at the power supply +OUT to -OUT terminals. Adjust with caution, as a trip will result if voltage is adjusted too high. To reset a trip, reduce the voltage adjustment, then cycle power.

Also verify Analog Inputs for + and – 15VDC supply in the PVF menu 3.5.

CAUTION: Adjusting output too high will cause the unit to trip.

7.8.2 Microprocessor Board
On the microprocessor board there are nine LED’s (light emitting diodes), five pushbuttons, and four switches. The On LED for the P8 or the Status LED for PIO9 microprocessor being on indicates that the board is running but not necessarily functioning normally. The eight remaining LED's (in a row) display error/status codes (the LCD display will display this information in English format when provided). In general, the car A/B switch toggles the function of the eight LED's as indicators for CAR A (if the switch is UP) or CAR B (if switch is DOWN). Note that CAR A/B switch is not used for V900 control systems. Refer to the Field Reprogramming Manual for more details on the use of microprocessor PC board switches.

WARNING: Do NOT depress the microprocessor-reset button while any car is running, as it will cause an emergency stop. Use extreme care.

A group of special conditions are recognized by the microprocessor. If one of these "errors" occurs, a code will be displayed corresponding to that condition. The microprocessor will scroll up to six errors at a time, which show on the LCD display. The eight LED array will display the error that needs too be corrected first, that is, the one with the highest priority. The field technician should look first to the LED array to identify the error that needs to be corrected first. Error codes can be found in Section 5 of this manual and on the inside of the control equipment enclosure door.

Not all system errors are detected and displayed by the P8 or PIO9; however, the most frequent errors have been programmed to be recognized. Even the fact that the door lock string is open, as it sometimes is during normal operation, is defined with an "error" code, which is frequently displayed during normal operation.
7.8.3 I/O-7 or PIO9 IO section, board (I/O-EX board)
The I/O board performs the task of buffering or protects the five volt computer logic environment from the electrically noisy 110 volt outside world. For this reason, most microprocessor system problems occur on the I/O boards.

The input buffer section of the I/O accepts high-level inputs from the HLS-7 board or car signals, and converts them to five volts computer signals. The I/O board also provides low-pass filtering to reduce noise susceptibility and Schmitt triggers to increase noise margin. The relay and signal driver sections of the I/O board provide high voltage switching outputs that actuate relays on the HLS-7 module and general elevator signals.

The output portion of the IO-7 or PIO9 or IO-EX is field replaceable. The replaceable components consist of an output Triac and a Zener diode, which can be identified by the corresponding LED number (i.e. LED 77 corresponds to Triac 77 and Zener diode Z77).

To determine if the Triac is bad, note that normal behavior of the output will be to turn on such signal as soon as power is applied to the controller. If the Zener diode is shorted, the output will not come on until the controller turns it on, and once turned on it will not be able to be turned off.

A Zener diode has the same characteristics as a standard diode. Using a standard multimeter on diode check mode, the diode shall conduct in one direction only, when the positive meter lead is placed on the anode side (non-belted side of the diode) and the negative lead on the cathode side of the diode, and shall not conduct if meter leads are reversed. If a diode conducts in both directions, it is shorted and needs to be replaced.

If a Zener diode requires replacement, remove it using a pair of pliers. Trim leads on the replacement diode to the proper length, and then carefully insert the new diode into position.
Section 8 – Group System

8.1 Detailed Explanation of Group Dispatching Subsystem
Since an elevator is a continuous, real-time machine, the supervisory control subsystem microcomputer (or microprocessor) is designed to operate in a loop, performing a predetermined pattern of instructions many times each second. Its speed is such that each elevator control function appears to be continuously monitored. The basic control loop and the functions performed by the computer during each portion of that loop are described below.

8.2 Data Acquisition
Before any logic decisions can be made data must be acquired during the first portion of the control loop called "contact scan." The microprocessor interrogates each input (hall calls, car calls, and power subsystem inputs) and saves the data in storage memory. This data is used during the rest of the control loop. In effect, the controller takes a "snapshot" of the entire elevator system, and then it makes decisions based on that information. Snapshots are made many times each second providing functionally continuous system monitoring.

8.3 Fireman’s Service
After data has been acquired, proper outputs are computed for fireman’s service.

8.4 Stepping
The next major block in the control loop deals with stepping. The system has no mechanical floor selector so, when power is first applied, the Supervisory Control system checks to see if the car is at the top landing (on the up slowdown limit) or at the bottom landing (on the down slowdown limit). If the car is at either of these locations the internal electronic "selector" is set to the proper value.

If the car happens to be somewhere mid-hoistway when power is first applied, the system will create a phantom call, and run the car until it reaches a terminal landing, whereupon it will become synchronized. After initial synchronization, magnetic vanes placed in the hoistway inform the Supervisory Control System when the car passes each floor. The internal electronic "selector" updates accordingly.

The stepping point is actually one slowdown distance ahead of each floor. When the car steps into any given floor, the control system determines if there are any calls registered for that floor, and if so, initiates a slowdown and cancels the calls. This method requires no mechanical attachments to the car, such as chains, wires, or tapes.

After the controller processes data pertaining to a moving car it scans all calls present and selects a direction preference for the car (if it is not already answering a call).
8.5 Door Operation
The next block in the control loop is concerned with door operation. While the car is running, this portion is bypassed, but when the car enters a door zone this block becomes active. Functions performed by the door-processing block include door holding times (hall call time, car call time, and shortened door time), door opening and closing, and permission to proceed at high speed. The car actually moves in response to signals generated during door control loop processing, since all interlocks and timers (as well as car panel button inputs) must be correct before car movement is allowed.

8.6 Indicator Lamps
The final block of the control loop uses data generated by all previous calculations and calls stored in memory to light the appropriate car panel and hall indicator lamps. Once this has been accomplished, the loop is completed and the processor starts the next contact scan.

The entire loop process is repeated many times each second for a smooth and, to all outward appearances, continuous operation.

It should be noted that the power-up logic, in addition to correctly presetting the floor selector memory location, clears all memory locations and output buffers prior to applying any signals to the power control subsystem, ensuring safe, stable operation.

Section 9 – Maintenance
9.1  Maintenance
The Elevator Controls Microprocessor Elevator Controller has been designed to require as little routine maintenance as possible. In fact, the mechanical interconnections are the least reliable portion of the solid-state system, and the less they are disturbed, the more likely the system is to continue to function properly.

The elevator itself, however, is a complex mechanical apparatus, and therefore requires periodic routine preventive maintenance. In addition to lubrication of the various moving parts, the door lock contacts should be cleaned and inspected regularly since the exposed contacts are susceptible to dirt and corrosion. The doors also receive the most wear, often making two or even three cycles at a floor.

The various rotating machinery belts and couplings should be routinely inspected for wear. Wear could cause loss of control of the elevator car.

If the elevator system develops problems or becomes inoperative refer to the Troubleshooting guide Section 7 of this manual.

9.2  Replacement Parts List

9.2.1  Elevator Controls PC Boards
1) P8 Main microprocessor board (Standard controllers only).
2) IO7-Vxx Main input-output board (Standard controllers only).
3) IOEX-B44 ASME-17.1A-2000 monitoring board (Standard controllers only).
4) IOEX-Vxx Input-output expander board.
5) PVF Pattern generator microprocessor board set Version 3, IO and Microprocessor boards or SDI Version 4 Board.
6) LSSM-5 Speed monitor board.
7) PIO9 Main microprocessor board (Prodigy controllers only).

For EZ-Link systems only
1) P8X  Controller to serial link microprocessor board (Standard controllers only).
2) TOC Car top microprocessor board.
3) COP Car panel microprocessor board.
4) Hall Microprocessor for hall stations.
5) COP/TOC-EX Car top or COP extender board.

NOTE: xx is the fixture voltage

9.2.2.  Relays
4 pole ice-cube 120 VAC
P&B    KHAU-17A12N-120

Appendix A1
Yaskawa F7 AC Vector Drive Unit

A1 Motor Drive Parameters

A1.1 Drive Parameters Overview

Review and become familiar with the YASKAWA F7 Drive User Manual. For simplified reference we will refer to it as the Drive Manual.

Pay particular attention to all safety precautions. Study the job prints, noting that the interface to the drive consists of basic drive inputs including:

a. Direction / run inputs
b. Speed signal input from PVF terminals PUP and GND
c. Power inputs to terminals R/L1, S/L2 and T/L3
d. Encoder inputs

The basic outputs are:

a. 3-Phase output to motor through contactor
b. Fault output (drops DSAF relay if a fault condition is detected)
c. Drive run output
d. ABS speed output

⚠️  CAUTION: Do not connect the building power supply directly to the motor contactor.

⚠️  WARNING: Power capacitors in the drive remain charged for some time after power is removed. Use care to prevent injury.

Familiarize yourself with the use of the drive's Digital Operator in the Drive Manual Chapter 3, including use of the keypad as described below.

Parameters may be accessed using the Quick Setting Menu (-QUICK-) which is used to set/read the most commonly used parameters or the Programming Menu (-ADV-) that is used to set/read every available drive parameter. The letters Q and A have been used, respectively, to indicate which mode is required to access each parameter.

🌐  NOTE: The Auto Tuning Menu (-A.TUNE-) can be used to auto-tune the motor drive. This function will calculate the required motor parameter settings for optimized motor performance. Auto-tuning is ideally performed with the motor disconnected from the load. When this cannot be accomplished, static or terminal resistance tuning can be done.
NOTE: Do not change any parameters except those found in the following tables. Other parameters are either not used in this particular application or are pre-programmed to EC default settings.

Verify that the parameters are as listed on the job-programming list supplied with the Elevator Controls job prints. Parameters listed below have been changed from the drive manufacturer defaults by Elevator Controls. Parameters noted (*) may need to be fine tuned during adjustment.

NOTE: Throughout the following procedures it will be necessary to match the actual car speed to the commanded car speed by adjusting the “motor speed” parameter.

The “Motor Speed” is adjusted, when required, by changing parameter H3-02 in the drive submenu Analog Inputs.

“Drive Gain” adjusts the sensitivity with which the drive follows the input signal without undesirable vibration or discomfort. “Drive Gain” is adjusted, when required, by changing the parameter C5-01 and C5-02 in the drive submenu ASR Tuning. EC ships the drive with drive gain preset to drive manufacturer defaults.

### A1.2 Drive Adjustments

#### System Constants

These drive parameters configure the drive for elevator control’s PVF operation behavior.

A1.3 Overspeed Using the Drive to Drive the Hoist Motor
These drive unit can be configured to run the hoist motor at a frequency larger than the hoist motor base input frequency to create an overspeed condition by manipulating parameters E1-04, Maximum Output Frequency.

a. To overspeed the car to 125% of contract speed perform following steps:
b. Place the car on Test Mode of operation.
c. Take the car to bottom landing.
d. Multiply the value in E-04 by 1.25 and program the result into E1-04.
e. Call the car via a car call to and intermediate landing, not the top landing.
f. Car will over speed to 125% of contact speed.
g. For down direction take the car to the top landing and call it to and intermediate landing, but not the bottom landing.

⚠️ WARNING: When performing an overspeed test. Make sure all parameters are **RESET TO THE ORIGINAL VALUE** when testing is completed.
Appendix A2
Magnetek HPV-900 AC Vector Drive Unit

A2 Motor Drive Parameters

A2.1 Drive Parameters Overview

Review and become familiar with the MAGNETEK HPV-900 Drive User Manual. For simplified reference we will refer to it as the Drive Manual.

Pay particular attention to all safety precautions. Study the job prints, noting that the interface to the drive consists of basic drive inputs including:

a. Direction / run inputs
b. Speed signal input from PVF terminals PUP and GND
c. Power inputs to terminals R/R1, S/S1 and T/T1
d. Encoder inputs

The basic outputs are:

a. 3-Phase output to motor through contactor
b. Fault output (drops DSAF relay if a fault condition is detected)
c. Drive run output
d. ABS speed output

⚠️ CAUTION: Do not connect the building power supply directly to the motor contactor.

⚠️ WARNING: Power capacitors in the drive remain charged for some time after power is removed. Use care to prevent injury

Familiarize yourself with the use of the drive's Digital Operator in the Drive Manual Parameters Section 3, starting on page 28, including use of the keypad as described below.

✏️ NOTE: The Adaptive Tune procedure can be used to auto-tune the motor drive. This function will calculate the required motor parameter settings for optimized motor performance. This procedure is explained in Section 5.7 of the HPV-900 Drive Manual.

There are two types of parameters, standard and hidden. Parameter access levels are set in the drive's Utility UO menu, parameter U2 – Hidden Items. Note that the hidden parameters are only accessible when U2 – Hidden Items is “enabled”.

Refer to Section 3.6 Utility U0 Menu in the Drive Manual for use of the utility functions.
**NOTE:** Do not change any parameters except those found in the following tables. Other parameters are either not used in this particular application or are pre-programmed to EC default settings.

Verify that the parameters are as listed on the job-programming list supplied with the Elevator Controls job prints. Parameters listed below have been changed from the drive manufacturer defaults by Elevator Controls. Parameters noted (*) may need to be fine tuned during adjustment.

**NOTE:** Throughout the following procedures it will be necessary to match the actual car speed to the commanded car speed by adjusting the “motor speed” parameter.

The “Motor Speed” is adjusted, when required, by changing parameter “SPD COMMAND MULT” in the drive submenu A1.

“Drive Gain” adjusts the sensitivity with which the drive follows the input signal without undesirable vibration or discomfort. “Drive Gain” is adjusted, when required, by changing the parameter “RESPONSE” in the drive submenu A1. EC ships the drive with drive gain preset to drive manufacturer defaults.

### A2.2 Drive Adjustments

### A2.3 Overspeed Using the Drive to Drive the Hoist Motor

The drive unit can be configured to run the hoist motor at a frequency larger than the hoist motor base input frequency to create an overspeed condition as follows:

1. Place the car on Test mode.
2. Take the car to terminal Landing.
3. Program parameter A1-16, Overspeed Multiplier to 125%, to allow the car to run at 125% of contract speed.
4. Under drive menu U0 select submenu OVRSPEED TEST U4, refer to section 3.6.4.3 of drive manual, Overspeed Test Via Operator, for detailed overspeed test description.
5. Place a Car Call several floors above/below floor to allow car to attain overspeed.
6. The drive will reset to non-overspeed mode when every time the run command is removed at the end of each run, repeat step 4 above for every test run required.

⚠️ **WARNING:** When performing an overspeed test. Make sure all parameters are **RESET TO THE ORIGINAL VALUE** when testing is completed.

📝 **NOTE:** When performing an overspeed test, note that an “OVERSPEED MULT” is included in the A1 submenu for simulating an overspeed condition. It is initiated through the Utility UO Menu. See Section 3.6.4.3 of the Drive Manual. Overspeed is automatically reset after each run.
Appendix A3
Magnetek HPV-600 AC Vector Drive Unit

A3 Motor Drive Parameters

A3.1 Drive Parameters Overview

Review and become familiar with the MAGNETEK HPV-600 AC Vector Elevator Drive, Technical Manual. For simplified reference we will refer to it as the Drive Manual.

Pay particular attention to all safety precautions. Study the job prints, noting that the interface to the drive consists of basic drive inputs including:

- Direction / run inputs
- Speed signal input from PVF terminals PUP and GND
- Power inputs to terminals R, S and T
- Encoder inputs

The basic outputs are:

- 3-Phase output to motor through contactor
- Fault output (drops DSAF relay if a fault condition is detected)
- Drive run output
- ABS speed output

⚠️ **CAUTION:** Do not connect the building power supply directly to the motor contactor.

⚠️ **WARNING:** Power capacitors in the drive remain charged for some time after power is removed. Use care to prevent injury

✍️ **NOTE:** The HPV-600 motor drive Adaptive Tune procedure can be used to autotune the motor drive. This function will calculate the required motor parameter settings for optimized motor performance. This procedure is explained in the ADAPTIVE TUNE section of the HPV-600 Drive Manual, pages 20-23.

✍️ **NOTE:** Adaptive tuning cannot be accomplished until adjustment per Section 3 of this manual has been completed.

Familiarize yourself with the use of the drive's Digital Operator in the Drive Manual Parameters Section, starting on page 37, including use of the keypad as described below.

There are two types of parameters, standard and hidden. Parameter access levels are set in the drive's Utility UO menu, parameter U2 – Hidden Items. Note that the hidden parameters are only accessible when U2 – Hidden Items is “enabled”.
Refer to the Utility Section U0 menu, page 127 in the Drive Manual for use of the utility functions.

NOTE: Do not change any parameters except those found in the following tables. Other parameters are either not used in this particular application or are pre-programmed to EC default settings.

Verify that the parameters are as listed on the job-programming list supplied with the Elevator Controls job prints. Parameters listed below have been changed from the drive manufacturer defaults by Elevator Controls. Parameters noted (*) may need to be fine tuned during adjustment.

NOTE: Throughout the following procedures it will be necessary to match the actual car speed to the commanded car speed by adjusting the “motor speed” parameter.

The “Motor Speed” is adjusted, when required, by changing parameter “SPD COMMAND MULT” in the drive submenu A1.

“Drive Gain” adjusts the sensitivity with which the drive follows the input signal without undesirable vibration or discomfort. “Drive Gain” is adjusted, when required, by changing the parameter “RESPONSE” in the drive submenu A1. EC ships the drive with drive gain preset to drive manufacturer defaults.

**A3.3 Overspeed Using the Drive to Drive the Hoist Motor**

The drive unit can be configured to run the hoist motor at a frequency larger than the hoist motor base input frequency to create an overspeed condition as follows:

1. Place the car on Test mode.
2. Take the car to terminal Landing.
3. Program parameter A1-14, Overspeed Multiplier to 125%, to allow the car to run at 125% of contract speed.
4. Under drive menu U0 select submenu OVRSPEED TEST U4, refer to page 111 of drive manual, Overspeed Test, for detailed overspeed test description.
5. Place a Car Call several floors above/ below floor to allow car to attain overspeed.
6. The drive will reset to non-overspeed mode when every time the run command is removed at the end of each run, repeat step 4 above for every test run required.

⚠️ **WARNING**: When performing an overspeed test. Make sure all parameters are **RESET TO THE ORIGINAL VALUE** when testing is completed.

آخر **NOTE**: When performing an overspeed test, note that an “OVRSPEED MULT” is included in the A1 submenu for simulating an overspeed condition. It is initiated through the Utility UO Menu. See Drive Manual page 109. Overspeed is automatically reset after each run.
Appendix A4
KEB Combivert F5 Motor Drive Unit

A4  Motor Drive Parameters

A4.1  Drive Parameters Overview
Review and become familiar with the KEB Combivert F5 Motor Drive Unit, Technical Manual. For simplified reference we will refer to it as the Drive Manual.

Pay particular attention to all safety precautions. Study the job prints, noting that the interface to the drive consists of basic drive inputs including:

- e. Direction / run input
- f. Speed signal input from PVF terminals VPAT and GND
- g. Power inputs to terminals L1, L2 and L3
- h. Encoder inputs

The basic outputs are:

- e. 3-Phase output to motor through contactor
- f. Fault output (drops DSAF relay if a fault condition is detected)
- g. Drive run output
- h. ABS speed output

⚠️ CAUTION: Do not connect the building power supply directly to the motor contactor.

⚠️ WARNING: Power capacitors in the drive remain charged for some time after power is removed. Use care to prevent injury.

Familiarize yourself with use of the motor drive's Digital Operator in the drive manual, Section 4 – Operation of the unit, to verify and/or set parameters.

🍃 NOTE: The KEB Combivert F5 Motor Drive Unit set up directions below are for Gearless Permanent Magnet AC motor applications.

🍃 NOTE: Do not change any parameters except those found in the following tables.
Other parameters are either not used in this particular application or are pre-programmed to EC default settings.

Verify that the parameters are as listed on the job-programming list supplied with the Elevator Controls job prints. Parameters listed below have been changed from the drive manufacturer defaults by Elevator Controls. Parameters noted (*) may need to be fine tuned during adjustment.
NOTE: Throughout the following procedures it will be necessary to match the actual car speed to the commanded car speed by adjusting the LF.11 parameter “Rater Motor Speed” parameter, value entered in motor RPM.

“Drive Gain” adjusts the sensitivity with which the drive follows the input signal without undesirable vibration or discomfort. “Drive Gain” is adjusted, when required, by changing the drive gain parameters LF.31, Proportional Gain, LF.32, Integral Gain, and LF.33 Gain Offset at Low Speeds. EC ships the drive with drive gain preset to drive manufacturer defaults.

NOTE: LF.28 parameter is used to set up encoder direction and motor rotation, with following configurations:

- **0** = Nothing Reversed
- **1** = A and B encoder channels swapped
- **2** = Motor Rotation Reversed
- **3** = Motor Rotation Reversed, and A & B encoder channels swapped.

A4.2.2 Drive Adjustments
The drive unit needs to measure several motor parameters for optimum performance as follows:

1. Measure the motor resistance:
   a. Set the controller in controller inspection mode of operation.
   b. Set LF.3 to conF, and remove the FB1 and FB2 fuses from brake circuit.
   c. Go to LF.18 and press FUNC key on drive keypad. The display should read Auto.
   d. Press the UP key on drive keypad. The display should read 50.000.
   e. Press and hold the Inspection UP controller switch, the motor contactor should pick, but the brake will not. Do not release the Inspection UP switch until procedure is completed. The Measurement will take 10 to 15 seconds and the drive will display ChEc.
   f. When the display changes to a numerical value or E.Cdd, release the Inspection Up Switch.
   g. If the change in display was to a numerical value the procedure was successful, skip to entry j below.
   h. If the change was to E.c.Cdd, try repeating procedure from step b above first, if not successful verify motor connections and try again.
   i. If unable to successfully complete procedure measure ohms from lead to lead and average results, use value to set parameter LF.18.
   j. Set LF.3 to Run, and install FB1 and FB2 fuses.

⚠️ CAUTION: Do not forget to set LF.3 to Run to enable drive to run.

2. Absolute Encoder Set Up, to accomplish this set up procedure refer to section 5.11, Running the Motor, in the drive manual, make sure to read complete section before starting to execute procedure

A4.3 Overspeed Using the Drive to Drive the Hoist Motor
The drive unit can be configured to run the hoist motor at a frequency larger than the hoist motor base input frequency to create an overspeed condition as follows:
   a. Place the car on Test mode.
   b. Take the car to terminal Landing.
   c. Program parameter LF.23 to next value.
   d. Place a Car Call several floors above/ below floor to allow car to attain overspeed.

📝 NOTE: Parameters LF.20 contract speed is in fpm, parameter the LF.21 sheave diameter in inches, parameter LF.22 gear ratio, and LF.23 roping ratio are used by the drive unit logic to scale the fpm contract speed value to the inverter's base unit of rpm. By increasing the roping ratio, this changes the scale to a higher rpm value for a given contract speed and also raises the inverter overspeed level, allowing an overspeed test on the elevator without tripping drive unit on overspeed fault.

⚠️ WARNING: When performing an overspeed test. Make sure all parameters are RESET TO THE ORIGINAL VALUE when testing is completed.
Appendix B1
Magnetek DSD-412 SCR Drive Unit

B1 Motor Drive Parameters

B1.1 Drive Parameters Overview
Familiarize yourself with Magnetek DSD 412 CS00407 Technical Manual. For simplified reference we will refer to it as the Drive Manual. Pay particular attention to all safety precautions. Study the interface to the drive on the job prints, and note that the basic inputs to the drive are:

- Direction / run inputs
- Speed signal input terminals from PVF terminals VPAT and GND
- Power inputs to terminals L1, L2, and L3
- Encoder input

The basic outputs are:

- Variable DC voltage output to motor through contactor
- Motor field control
- Fault output, drops DSAF relay if fault
- Drive Run output
- ABS Speed output

⚠️ CAUTION: Do not connect building power supply to motor contactor.

✏️ NOTE: Verify that the parameters are as listed on the job-programming list supplied with the elevator controller job prints page 4 within the drive unit block diagram interface area.

Familiarize yourself with the drive's STANDARD CONTROL / DISPLAY OPERATION, pages 35 to 45 of drive manual.

✏️ NOTE: Parameters that are not listed in the following tables may not be used, or are used as programmed per the factory default value. Verify that the parameters are as listed on the job-programming list supplied with the elevator controller job prints.

Parameters listed below have been changed from the factory defaults by Elevator Controls. Parameters noted (*) may need to be fine tuned during adjustment. Page 40 details the use of function #994 to save any changed value. Any changes or adjustments will be returned to previous values if power is turned OFF or the drive is reset unless saved by setting function #994 with the NVRAM switch in the proper position.
NOTE: Thru the following procedures it will be necessary to match the actual car speed to the commanded car speed by adjusting the “motor speed”. The performance of the drive in following the input signal, to minimize vibration or passenger discomfort, is adjusted using “drive gain”.

The “motor speed” is adjusted, when required, by changing parameter Function #11, Motor RPM. The “drive gain” is adjusted, when required, by changing Function #42, Stiffness. Drive gain factory settings have been used as initial settings.

NOTE: The SCR Drive “Ready” light and output is not sensitive to input power phase rotation, but they will fault if one or more phases are lost.

NOTE: Motor and Brake information shown on page 4 of prints, Field Data table, was generated based on information provided to Elevator Controls and must be verified against actual Motor and Brake data tags or field measured values.
NOTE: It is necessary to tune the SCR Drive to the motor. Perform a drive SELF-TUNE operation, function #997, refer to page 42; The motor contactor will energize, and current will flow to the motor armature but the car will not be required to move during this procedure.

B1.3 Overspeed Using the Drive to Drive the Hoist Motor
The drive unit can be configured to run the hoist motor at a frequency larger than the hoist motor base input frequency to create an overspeed condition.

WARNING: When performing an overspeed test. Make sure all parameters are RESET TO THE ORIGINAL VALUE when testing is completed.

Overspeed Test – Function #81 has been set to run the elevator at 140 % of rated speed for overspeed testing. Function #80 turns the effect of that multiplier on and off. However, be aware that the drive overspeed trip fault set by function #12 will be tested and will trip. To insure that the drive overspeed test does not interfere with the governor test, function #12 must also be increased during the governor overspeed test. After testing, be sure function #12 is retuned to its original value and that function #80 is set to 0, Off.
Appendix B2
Control Techniques Mentor II SCR Drive Unit

B2  Motor Drive Parameters

B2.1  Drive Parameters Overview
Familiarize yourself with Control Techniques Inc, Mentor II Technical Manual. For simplified reference we will refer to it as the Drive Manual. Pay particular attention to all safety precautions. Study the interface to the drive on the job prints, and note that the basic inputs to the drive are:

a. Direction / run inputs
b. Speed signal input from PVF terminals VPAT and GND
c. Power inputs to terminals L1, L2, and L3
d. Encoder or Analog Tachometer input

The basic outputs are:

a. Variable DC voltage output to motor through contactor
b. Motor field control
c. Fault output, drops DSAF relay if fault
d. Drive Run output
e. ABS Speed output

─ CAUTION: Do not connect building power supply to motor contactor.

─ NOTE: Verify that the parameters are as listed on the job-programming list supplied with the elevator controller job prints page 4 within the drive unit block diagram interface area.

─ NOTE: Parameter 0.00 data must be set to 200, or to a specific security code, to satisfy security requirements before any changes or adjustments can be made.

─ NOTE: Through the following procedures it will be necessary to match the actual car speed to the commanded car speed by adjusting the “motor speed”. The performance of the drive in following the input signal, to minimize vibration or passenger discomfort, is adjusted using “drive gain”. Be sure that switches SW 1, B thru H are in the proper position; B to D are used for encoder, F to H for tachometer, only one at a time can be on.

The “motor speed” is adjusted, when required, by adjusting RV1 Potentiometer in Mentor II drive unit clockwise to increase elevator Speed, and counter-clockwise to reduce elevator speed for DC tachometer feedback systems, or by adjusting parameter 3.14, Encoder Feedback Scaling, for encoder feedback systems, please
refer to drive manual Menu 03 parameter 3.14 formula calculation for reference on this parameter value, increasing the parameter value will decrease car speed.

NOTE: Parameters listed below have been changed from the factory defaults by Elevator Controls. Parameters noted (*) may need to be fine tuned during adjustment.

NOTE: Any change or adjustment of parameters will be returned to the previous value if power is turned off or the drive is reset unless saved by setting the parameter 00.00 data to “001” and pressing “RESET”.

NOTE: It is advisable to tune the SCR Drive to the motor for optimum performance. To perform an auto-tune of the current loop, set parameter 05.27 = 1, run the elevator up and down for several seconds, set parameter 05.14 = parameter 05.13, reset parameter 05.27 = 0, record and save parameters.

“Drive Gain” adjusts the sensitivity with which the drive follows the input signal without undesirable vibration or discomfort. Drive Gain” is adjusted, when required, by changing the parameters 3.09, Speed Loop Proportional Gain, and 3.10, Speed Loop Integral Gain. Incrementing the values of these parameters will make the drive more responsive. Initially the drive gain has not been changed from the drive factory setting.

B1.3 Overspeed Using the Drive to Drive the Hoist Motor
The drive unit can be configured to run the hoist motor at a frequency larger than the hoist motor base input frequency to create an overspeed condition.

⚠️ WARNING: When performing an overspeed test. Make sure all parameters are RESET TO THE ORIGINAL VALUE when testing is completed.

Overspeed Test – The elevator will need to be set to run at 140% of rated speed for overspeed testing. Set Encoder feedback by setting parameter 3.14 to a value equal to rated speed divided by 1.4. Set Tachometer feedback using Potentiometer RV1, which must be increased (turn clockwise to increase) so that the car runs 1.4 x Rated Speed. The position of potentiometer RV1 can be monitored at parameter 3.26 with car running at rated speed. Record this value to allow it to be correctly reset after the Overspeed Test. After testing, be sure parameter 3.14 or potentiometer RV1 are retuned to original values.
Appendix  B3  
Two Stop Loaded Car Buffer & Counterweight Empty Car Test

B3.a  Car Buffer Test – Fully Loaded Car 

a. Place a full load in the car; place the controller test and inspection switches in the test position. 
b. Move to the top floor, or several feet up from the bottom floor sufficient to allow 
reaching contract speed when running test down. 
c. Refer to SDI Manual, Program Variables Menu and record the current settings for 1.1 
Contract Speed, 1.3 Initial Jerk, 1.4 Roll Over Jerk, 1.5 Deceleration Jerk, 1.7 
Acceleration, 1.8 Deceleration, and 1.12 Inspection Speed. Now Temporarily 
program 1.1 Contract Speed and 1.12 Inspection Speed to 50 FPM, and all Jerk and 
Acceleration/Deceleration parameters 1.3, 1.4, 1.5, 1.7, and 1.8 to 25 FPM. 
Additionally, refer to the drive parameter section and increase acceleration parameter 
to 3 seconds for contract speeds up to 350 FPM and 6 seconds for up to 700 FPM to 
soften up ramping up to speed during the test. Return this value to original setting 
when done with this test. 
d. Disable LSSM tripping by removing Jumper SH2 temporarily. 
e. Jumper terminal 4A to all down slowdown switches terminals (DSD1, DSD2, and 
DT6 thru DT14 to bypass all present down slowdown switches as required. 
f. Place a jumper from controller terminals 17 to 23 to bypass safety switches. Place a 
jumper from controller terminals 29 to 33 to bypass the down normal limit switch. 
g. Run car down on inspection to run it into the buffer (once you start down on 
inspection do not stop until car is run into buffer, as drive may fault due to abrupt 
stop on inspection). After the car strikes the buffer, and drive sheave slips under the 
cables release inspection run down activation. Restore all SDI parameters and drive’s 
acceleration to values recorded in step c. above. Run the car up to the bottom landing 
doors zone area and REMOVE ALL JUMPERS PLACED IN THE PROCEDURE 
DESCRIBED ABOVE. Restore SH2 jumper above. 

⚠️ NOTE: The SDI microprocessor board will open the safety string after detecting the 
pulse count failure caused by the buffer test. Reset the SDI after the buffer test is 
completed and the car is stopped to restore safety circuits to normal operation.

B.3.b  Counterweight Buffer Test – Empty Car 

a. Place a full load in the car; place the controller test and inspection switches in the test position. 
b. Move to the bottom floor, or several feet down from the top floor sufficient to allow 
reaching contract speed when running test up. 
c. Refer to SDI Manual, Program Variables Menu and record the current settings for 1.1 
Contract Speed, 1.3 Initial Jerk, 1.4 Roll Over Jerk, 1.5 Deceleration Jerk, 1.7 
Acceleration, 1.8 Deceleration, and 1.12 Inspection Speed. Now Temporarily
program 1.1 Contract Speed and 1.12 Inspection Speed to 50 FPM, and all Jerk and Acceleration/Deceleration parameters 1.3, 1.4, 1.5, 1.7, and 1.8 to 25 FPM.

Additionally, refer to the drive parameter programming section and increase acceleration parameter to 3 seconds for contract speeds up to 350 FPM and 6 seconds for up to 700 FPM to soften up ramping up to speed during the test. Return this value to original setting when done with this test.

d. Disable LSSM tripping by removing Jumper SH2 temporarily.

e. Jumper terminal 4A to all up slowdown switches terminals (USD1, USD2, and UT6 thru UT14) to bypass all present down slowdown switches as required.

f. Place a jumper from controller terminals 17 to 23 to bypass safety switches. Place a jumper from controller terminals 28 to 30 to bypass the up normal limit switch.

g. Run car up on inspection to run counterweight into the buffer (once you start up on inspection do not stop until counterweight is run into buffer, as drive may fault due to abrupt stop on inspection). After the counterweight strikes the buffer, and drive sheave slips under the cables release inspection run up activation. Restore all SDI parameters and drive’s acceleration to values recorded in step c. above. Run the car down to the top landing door zone area and REMOVE ALL JUMPERS PLACED IN THE PROCEDURE DESCRIBED ABOVE. Restore SH2 jumper above.

NOTE: The SDI microprocessor board will open the safety string after detecting the pulse count failure caused by the buffer test. Reset the SDI after the buffer test is completed and the car is stopped to restore safety circuits to normal operation.
